Sixth Annual Year Book

AMERICAN PUBLIC HEALTH ASSOCIATION

1935-1936

AMERICAN PUBLIC HEALTH ASSOCIATION
50 WEST 50TH STREET, NEW YORK, N. Y.

CONTENTS

Foreword to Sixth Annual Year Book

WHEN the first *Year Book* of the American Public Health Association was presented to the membership in 1931, it was a device calculated to accomplish two purposes; first, prompt publication of scientific committee reports read at the Annual Meeting under one cover rather than in scattered installments throughout the year; and second, to release the two hundred odd pages of the *Journal* previously given over to committee reports for the admission of timely contributed articles having no Annual Meeting origin.

A considerable volume of material representing cumulative and current information relating to the Association which the *Journal* had carried heretofore seemed more appropriate for publication in the *Year Book*, and was accordingly included—such things as the Constitution and By-laws, lists of committees, and section councils, the report of the Executive Board to the Governing Council, etc.

This pattern was followed without alteration for 5 years, while a picture was forming in the minds of the Editorial Committee of what the *Year Book* could be in order to render its best service to the membership. There finally evolved a conception of the *Year Book* as a depository of the things mentioned above and also of certain information significant to health workers and classified as—unobtainable elsewhere, accessible elsewhere from sources not generally familiar, or perhaps easily available but worth repeating for constant and ready reference. Obviously, to include all would be to attempt to bind the Surgeon-General's Library in one volume. We can begin modestly, however, to add to the *Year Book's* usefulness, and this year it is presented with several new sections.

The lists of state, county, and city health officers are included, with indications of American Public Health Association membership affiliations. Other innovations are: a list of universities in the United States and Canada conferring public health degrees, together with brief statements of entrance requirements; a list of American foundations making grants of amounts in excess of $5,000 for medical and public health purposes in 1934; a list of cities surveyed by the American Public Health Association; lists of winning and honorable mention cities and counties in the Rural and City Health Conservation Contests.

The only omission over previous years is the report of the Executive Board to the Governing Council. This is a lengthy mimeographed document which has been distributed in full to the members of the Council. It covers in detail the work of the administrative office and of the five standing committees. Its permanent value outside the Association's archives is questioned, and it is, therefore, omitted from the 1935–1936 *Year Book*. Copies are available in the headquarters office and will be sent upon request to anyone interested.

Suggestions from the membership are invited for future *Year Book* improvements. They will be considered for inclusion in later volumes providing they have value for a fair segment of the total membership.

The American Public Health Association

Its Objectives and a Pledge of their Attainment

OUR permanent objective is the effective control of preventable disease, and the security of health for all the people.

The first necessity to attain this objective is:

A full-time health service with trained personnel for every community, and provision of adequate public funds for its support.

The first fruits of such organization and support of public health knowledge and resources will be:

1. Reduction of the maternal mortality rates, so that the United States and Canada will be second to no nation in the safety of motherhood.
2. Securing normal growth of body and mind for children, and their training in the laws and personal practices of a healthy life.
3. Protection of life and limb and promotion of health for the working man and woman.
4. An adequate supply of safe milk for every community.
5. An adequate supply of pure water for every community.
6. Elimination of tuberculosis, malaria, hookworm disease, typhoid fever, diphtheria and smallpox, among the communicable diseases of which we have sufficient knowledge.

The American Public Health Association pledges to the health workers of the country and to the people of our member nations vigorous coöperation in carrying these projects to a successful conclusion.

CONSTITUTION AND BY-LAWS
AMERICAN PUBLIC HEALTH ASSOCIATION

As Adopted at the Fifty-eighth Annual Meeting, and Amended at the Sixty-fourth Annual Meeting

CONSTITUTION

ARTICLE I Name

The name of this Association, incorporated under the laws of Massachusetts, is the American Public Health Association.

ARTICLE II Object

The object of this Association is to protect and promote public and personal health.

ARTICLE III Governing Council

A. *Composition:* There shall be a Governing Council consisting of:

1. The officers of the Association.

2. Thirty members of the Council, to be elected by and from the Fellowship of the Association, for three-year terms, one-third retiring each year. These members of the Council shall be nominated and elected as provided for in the By-laws.

If one of these members is elected a Section Chairman, Vice-Chairman, or Secretary, or appointed the representative of an Affiliated Society, a new Councilor to fill such vacancy shall be elected by the Governing Council.

3. The Chairman, Vice-Chairman, and Secretary of each Section.

4. Representatives to be appointed by Affiliated Societies as provided for in the By-laws. Such representatives shall be Fellows of the American Public Health Association.

5. The elective members of the Council of the Health Officers Section.

6. A representative to be designated by each regional branch. Such representative shall be a Fellow of the American Public Health Association.

B. *Terms:* Terms of Councilors shall begin at the end of the annual meeting when elected, and shall terminate at the end of the annual meeting at expiration of term; provided that Councilors shall have the right to attend meetings of the Council in an advisory capacity as soon as elected.

C. *Reëlection:* After two consecutive terms, an elective Councilor shall be ineligible for reelection to the Council during one Association year.

D. *The Officers of the Association* shall be the officers of the Council.

E. *Functions:* The functions of the Council shall be:

1. To establish policies for the Association and for the guidance of the Executive Board and the officers.

2. To establish Sections of the Association; to combine or discontinue them when necessary; to maintain coördination among them; and to formulate general rules governing the policies of the Sections.

3. To submit to the vote of the Association all resolutions which have received the approval of the Governing Council.

4. To elect and establish qualifications for Affiliated Societies, Fellows, and Honorary Fellows as provided in the By-laws.

5. To elect the Executive Board and the officers of the Association.

6. To receive from the Executive Board at its first session, at the time and place of the annual meeting of the Association, a definitely formulated statement of a program of the major activities proposed for the ensuing year. To determine at the annual meeting of the Association in general outline the allocation of Association moneys in the budget for the ensuing year. To require a report from the Chairman of the Executive Board in which the work, the accomplishments and the financial status of the Association during the year preceding such annual meeting shall be reviewed.

7. To publish after each of its meetings an abstract of the minutes of such meetings.

F. *A Quorum* of the Council shall consist of ten Councilors.

G. *Meetings* of the Council shall be called by the Executive Secretary at the request of the President, or at the request in writing of any twelve Councilors. In the latter case, the call to meeting, issued at least twenty days in advance, shall state the purpose of the meeting.

ARTICLE IV Officers

The officers of this Association shall be a President, a President-elect, three Vice-Presidents, an Executive Secretary, a Treasurer, and the Chairman of the Executive Board. The officers, with the exception of the Chairman of the Executive Board and the Executive Secre-

tary, shall be elected by written ballot of the Governing Council as provided in this article and in the By-laws. The President-elect shall serve as such from the close of the annual meeting at which he was elected to the close of the next annual meeting, when he shall automatically become President. As President he shall serve to the close of the next succeeding annual meeting. Other officers shall serve from the close of the annual meeting when elected, until the close of the next annual meeting, and all officers shall serve in any case until their successors are elected and qualified. A majority vote of the Councilors voting shall be required to elect, and if no candidate receives a majority vote on the first ballot, the candidate receiving the smallest number of votes shall be dropped after each ballot in succession until a majority vote is obtained. The Chairman of the Executive Board and the Executive Secretary shall be elected by the Executive Board, which Board shall define the duties and authority of these officers, respectively.

ARTICLE V AMENDMENTS

This Constitution may be amended by a two-thirds vote of the Fellows of the Association present and voting at an annual meeting, provided that the specific amendment to be acted upon is published in the official publication of the Association not less than thirty days prior to the meeting, and provided further that the amendment has received the approval of the Governing Council.

BY-LAWS

ARTICLE I MEMBERSHIP AND DUES

A. There shall be seven classes of constituents. Of these, Fellows may be elected only from the United States, Canada, Mexico and Cuba. The other six classes of constituents may be elected from any country. The respective appellations, qualifications for election, and dues shall be as follows.

1. *Fellows:* Only professional health workers, from the United States and its possessions, Canada, Mexico and Cuba, who have been Members of the Association for at least two years, and of established professional standing (whether employed by public or private agencies or in independent private practice), shall be eligible for election as Fellows, provided that a Member shall be not less than thirty years old at the time the application for Fellowship is made, and provided, further, that the following persons shall be considered to have an established standing in the profession of public health, namely:

a. A person who has attained the degree of Doctor of Public Health, Doctor of Science in Public Health, Doctor of Philosophy in Public Health, or other equivalent degree, according to standards approved by the Executive Board of the American Public Health Association.

b. A person who has attained an academic or professional degree involving training in public health, and who has been regularly engaged in public health work for four years, having rendered meritorious service in the public health profession, either as a health officer or in responsible charge of work in a state or municipal department of health or other official public health organization.

c. A person who has done notable original work in public health or preventive medicine of a character to give him a recognized standing equivalent to that required for Fellows under paragraphs "a" and "b."

d. A person regularly engaged in public health work for at least five years, who has given evidence of special proficiency in the service of an official or unofficial public health organization, and who has attained a professional standing equivalent to that required for Fellows under paragraphs "a" and "b."

e. A teacher of public health or one of its constituent sciences. As such he shall have attained distinction as an expounder of the principles of public health or its constituent sciences and he shall have had at least five years' experience as a teacher of public health subjects. Any years of experience as defined in paragraphs "b" and "d" that the applicant may have had shall be considered the equivalent of the same number of years experience as a "teacher."

f. A person not covered by the above, who has made substantial contributions to public health work in his chosen branch of public health service, and who has attained a professional standing equivalent to that required for Fellows under paragraphs "a" and "b."

The application for Fellowship shall be made on an approved form and shall be sponsored by two Fellows of the Association who shall be Fellows of the Section with which affiliation is desired, provided, however, that when affiliation with a Section is not desired, the sponsors may be any two Fellows in good standing in the Association. Fellows without Section affiliation shall be known as unaffiliated Fellows.

When the application has been duly sponsored and otherwise completed, it shall be transmitted to the Administrative Office of the Association, which shall make note thereon of such knowledge as it may have concerning the standing of the applicant in the Association. The application shall be forwarded by the Administrative Office to the Secretary of the Section in which affiliation is desired, for the approval of the Section Council, and when acted upon by the Section Council, it shall be returned to the Administrative Office by the Secretary of the Section, after he has made endorsement on the application of the action of the Section Council. When the application is for unaffiliated Fellowship, the Executive Board of the Association shall act in place of the Section Council. When the application has been approved by a majority of the Section Council or the Executive Board, as above provided, it shall be voted upon by the Governing Council, provided the name of the applicant shall have been officially published at least fifteen days in advance, and provided further that the application shall have been approved by the Committee on Fellowship and Membership

A Fellow may belong to and vote in only one Section, but such affiliation may be transferred to another Section if approved by vote of a majority of the Council of the latter Section. Unaffiliated Fellows may become affiliated with a Section if approved by vote of a majority of the Council of the Section with which affiliation is desired.

The right to hold office or to serve as chairman of a committee in the Association shall be limited to the Fellows of the Association, whether Section Fellows or unaffiliated Fellows. The right to hold office or to serve as chairman of a committee in a Section shall, however, be limited to the respective Fellows in such Section. This provision shall not prevent the election of a Vice-President of the Association who may not be a Fellow.

The dues of Fellows shall be $10.00 per year.

2. *Honorary Fellows:* Honorary Fellows may be elected by the Governing Council for distinguished service in public health. Honorary Fellowship shall not include voting power or payment of dues.

3. *Members:* Persons professionally engaged or interested in public health work shall be eligible for election as Members when sponsored by two Fellows of the Association. They may serve on committees, except as chairmen. Dues $5.00 per year. A Member may belong to only one Section, but such affiliation may be transferred to another Section if approved by vote of a majority of the Council of the latter Section. Unaffiliated Members may become affiliated with a Section if approved by vote of a majority of the Council of the Section with which affiliation is desired.

4. *Sustaining Members:* Individuals or corporations interested in public health may be elected to Sustaining Membership. Dues $50.00 or more per year.

5. *Affiliated Societies:* A state or provincial public health association or similar regional society including more or less than a state, primarily composed of professional public health workers and organized for the same general objects as the American Public Health Association, may be elected as an Affiliated Society, provided that not less than twenty of its active members and at least one-half of its active members are Members or Fellows of the American Public Health Association. Not more than one such society shall be admitted from the same area.

A society applying for affiliation shall submit a copy of its constitution and by-laws, its last annual budget, a roster of its members and such other evidences of its qualifications as may be required. It shall submit annually and at other times such reports on its financial standing, membership and other matters as may be required by the Executive Board of the American Public Health Association.

The Committee on Fellowship and Membershall shall consider all applications for affiliation and report its recommendations to the Governing Council.

The annual dues of Affiliated Societies shall be one per cent of their gross annual income, the minimum dues per society being $10.00 per year.

Each Fellow, Member, and Affiliated Member of the American Public Health Association shall be a member of the Affiliated Society to which he is eligible and no person eligible for election to an Affiliated Society shall be admitted to Membership, or Affiliated Membership in the American Public Health Association unless such person has qualified or at the same time qualifies as a member of an Affiliated Society.

For every Fellow, Member, or Affiliated Member paying annual dues to the American Public Health Association, the American Public Health Association shall remit to the Affiliated Society of which such person is a member the sum of $1.00 per annum.

6. *Affiliated Members:* This class of membership shall include all active (namely professional) members of Affiliated Societies, and in areas where no Affiliated Societies exist such other professional sanitarians as may be elected to this grade. Dues $1.00 per year.

7. *Life Members:* Upon the recommenda-

tion of the Committee on Fellowship and Membership any individual member of the Association may be elected a member for life. Election to this grade shall not affect the privileges held by such individual in his previous grade of membership. The dues for Life Members shall be $100.00, payable within one year after election, and this payment by such member shall exempt him from any further dues.

8. *Regional Branches:* The Governing Council may at its discretion establish regional branches of the Association.

B. *Election:* The election of Fellows (see A1 above), Honorary Fellows Life Members, and Affiliated Societies shall be by the Governing Council.

The election of Members and Sustaining Members shall be by the Executive Board.

Three-fourths of the votes cast shall be requisite for election.

Upon the recommendation of the Committee on Fellowship and Membership the Governing Council may discontinue the Membership, Fellowship or affiliation of any constituent. Three-fourths of the votes cast shall be necessary for such action.

C. *Dues:* Dues are payable annually in advance. All constituents paying dues shall be entitled to receive the AMERICAN JOURNAL OF PUBLIC HEALTH and, or, such other publications as may be designated by the Executive Board, which shall determine the proportion of dues to be devoted to this purpose.

Constituents of any class whose dues are unpaid for six months or more shall be considered not in good standing. Constituents not in good standing shall not be entitled to vote, hold office or enjoy other privileges or powers of membership. Good standing may be resumed upon the payment of all arrears and dues in advance for one year, provided, however, the lapsed period is not greater than one year. The Administrative Office shall notify by registered mail all constituents who have been in arrears for a period of eleven months. The names of constituents in any class whose dues remain unpaid for one year or more shall be presented to the Executive Board which shall order the names of such constituents stricken from the Membership roll, provided, however, such constituents have been duly notified as hereinbefore provided in this paragraph. Constituents whose names have been stricken from the rolls in this manner may be again admitted in the manner provided for the election of new constituents in the class for which they make application, provided such person or organization complies with the eligibility requirements at the time the new application is made.

If, in the opinion of the Executive Board, any member or Fellow of the Association be found (hereafter) to have permitted the use of his name, or otherwise to have allowed himself to be quoted or used for illustration in the advertising of a commercial product, in such a manner as to reflect discredit upon the Association, his Fellowship or Membership in the Association shall thereupon be terminated. The application of this article shall not be retroactive.

ARTICLE II GOVERNING COUNCIL

The thirty members of the Governing Council designated in Article III, Section A, Paragraph 2 of the Constitution, shall be nominated and elected as follows: There shall be a Nominating Committee composed of one Fellow elected by each Section at the preceding annual meeting, and an additional Fellow designated by the Executive Board, the latter serving as Chairman. This committee shall present to the Administrative Office at least two months before the next annual meeting the names of at least twenty and not more than thirty Fellows of the Association selected with due regard to geographical and Membership considerations as nominees for the Governing Council. The Administrative Office shall publish this list to the Membership. Upon the petition of twenty-five Fellows the Nominating Committee shall add the name of any Fellow to this list provided such petition is received fifteen days before the annual meeting. The time for closing the polls shall be determined each year by the Executive Board. The Fellows receiving the highest number of votes on a written ballot cast by the Fellows present and voting at the annual meeting shall be declared elected to fill existing vacancies. Should two or more candidates receive the same number of votes, the Executive Board shall, when necessary, determine by written ballot the order of precedence.

ARTICLE III EXECUTIVE BOARD

A. *Composition:* There shall be an Executive Board of nine members elected by the Governing Council, six of whom shall be past or present members of the Governing Council, and three of whom shall be the President, the President-elect, and the Treasurer.

1. When a Fellow accepts membership on the Executive Board, any position he may hold on any of the standing committees of the Association will thereupon automatically become vacant. This provision will become effective with the close of the annual meeting at which this amendment is adopted, at which time Fellows holding memberships on the Executive Board and any standing com-

mittees will indicate their preference for one or the other.

2. If a vacancy on the Executive Board shall occur after the annual meeting because of the preference of an elected member to retain his standing committee membership, the President shall designate a nominating committee for this purpose from the membership of the Governing Council and this committee shall nominate not less than three candidates for the vacancy, from whom the candidate receiving the highest number of votes in a mail ballot by the Governing Council shall be declared elected to the Executive Board to fill the vacancy.

B. *Terms:* The terms of the President, the President-elect, and the Treasurer as Executive Board members shall be one year each. The terms of the other members shall be three years each, expiring in rotation, two each year. The members of the Executive Board whose terms have not expired shall at the time of the adoption of this amendment continue in office until the expiration of the term for which they have been elected. At the annual meeting at which this amendment is adopted one member shall be elected for a term of two years and two members for a term of three years. Should a vacancy occur the Governing Council shall elect a member to fill such vacancy for the unexpired term. The terms of the members of the Executive Board shall begin at the end of the annual meeting at which they have been elected, and shall continue until the end of the annual meeting at expiration of term, provided that newly elected members of the Board shall have the right to attend meetings as soon as elected, and shall have no vote until installed.

C. *Reëlection:* After two consecutive terms of three years a member of the Executive Board shall be ineligible for reëlection during one Association year. This provision shall not apply to an officer of the Association.

D. *Officers:* The Executive Board shall elect from its own membership a Chairman who shall serve in that capacity for such term as the Executive Board shall determine. It shall also designate such other officers of the Board as it may require for the conduct of its business.

E. *Duties:*

1. To direct the administrative work of the Association.
2. To act as Trustee of the Association's properties.
3. To plan methods for the procurement of funds.
4. To recommend budgets for the Association's work
5. To conform to the policies of the Governing Council in the conduct of its work.
6. To appoint the members of the five Standing Committees and to authorize and confirm the appointment of all other Association committees.
7. To transmit a report of its proceedings and transactions to the Governing Council at least thirty days before each annual meeting.
8. In general to carry out the policies of the Governing Council between meetings of the latter.

F. *A Quorum* of the Executive Board shall consist of four members.

ARTICLE IV OFFICERS

The officers elected by the Governing Council shall be nominated from the floor by that body.

ARTICLE V COMMITTEES

There shall be five standing committees of the Association as follows:

1. Committee on Fellowship and Membership.
2. Committee on Meetings and Publications.
3. Committee on Administrative Practice.
4. Committee on Research and Standards.
5. Committee on Professional Education.

A. *Organization:* All of the Standing and Special Committees of the Association shall be authorized and appointed by the Executive Board unless otherwise provided for in these By-laws. Unless otherwise provided for all Section Committees shall be named by the respective Sections, and the personnel of such committees shall be confirmed by the Executive Board. The appointments of all Association and Section Committees unless otherwise provided for in these By-laws shall expire at the next annual meeting. The Chairmen of the Standing Committees shall be designated by the Executive Board. The Standing Committees shall designate from among their membership such other officers as they may require for the conduct of their business. Each committee shall control its policies within limitations prescribed by the Governing Council and the Executive Board.

The Executive Secretary shall be a member, ex-officio, of all standing Committees, and shall serve as Secretary of each such committee.

B. *Composition and Functions:*

1. The Committee on Fellowship and Membership shall consist of one Fellow to be elected by each Section and an additional Fellow elected by the Executive Board. At the time of the adoption of this amendment the Executive Board shall designate which

five of the members of this committee shall serve for one year, the balance to serve for two years. Thereafter, those designated to fill vacancies shall serve for a term of two years.

This committee shall pass upon the eligibility of Fellows, Members and other constituents, in accordance with the provisions of the By-laws. It shall carry on membership promotion and shall discharge such other duties as are assigned to it by the Governing Council or by the Executive Board.

2. The Committee on Meetings and Publications shall consist of five Fellows. At the time of adoption of this amendment the Executive Board shall elect five Fellows to serve for one, two, three, four and five years respectively. Thereafter, members shall serve for a term of five years.

This committee shall prepare plans and a program for the conduct of annual and other meetings of the Association. All publications of the Association, its Sections and committees shall be issued under the direction of this committee, which shall also be responsible for the editorial and financial policies and management of all such publications.

3. The Committee on Administrative Practice shall consist of fifteen Fellows as follows: Twelve shall be designated by the Executive Board to serve for a term of four years, the terms of three members of this committee expiring each year. The remaining three members of this Committee shall be elected annually by and from the Fellows of the Association, affiliated with the Health Officers Section.

This committee shall engage in the collection of information regarding current public health practices and analyze the material obtained to derive standards of organization and achievement. The findings and standards may be made available to public health workers through publications, information and field service under such conditions as the committee may establish. No standards shall be promulgated as the official and authorized judgment of the Association except with the approval of the Governing Council.

4. The Committee on Research and Standards shall consist of fifteen Fellows representative of the various Sections of the Association appointed by the Executive Board. In the beginning the Executive Board shall designate five who shall serve for a term of one year, five for two years, and five for three years. Thereafter members shall serve for a term of three years.

This committee shall be responsible for carrying out research and the development of standards in the technical branches of public health service, and coördinate such research and standardization. This committee shall also be charged with the duty of reviewing from time to time standards already established. No standards shall be promulgated as the official and authorized judgment of the Association except with the approval of the Governing Council.

5. The Committee on Professional Education shall consist of ten Fellows appointed by the Executive Board. At the time of the adoption of this amendment the Executive Board shall appoint ten Fellows, two to serve for one, two for two, two for three, two for four and two for five years respectively. Thereafter, members shall serve for a term of five years.

This committee shall be responsible for carrying out research and the development of standards for professional education and training in public health work and shall perform such other functions as may be delegated to the committee by the Governing Council with the view of maintaining professional qualifications of high standard. No standards shall be promulgated as the official and authorized judgment of the Association except with the approval of the Governing Council.

ARTICLE VI MEETINGS OF THE ASSOCIATION

There shall be at least one annual meeting of the Association, held at a place to be selected by the Governing Council. All papers and reports presented at the annual meeting and other meetings, including regional meetings, shall be the property of the Association for publication, unless this right is waived by the Committee on Meetings and Publications. Special meetings of the Association may be called by a majority vote of the Governing Council, the Executive Board, or the Association.

ARTICLE VII SECTIONS

The Executive Board shall approve rules and regulations relating to the government of the Sections, and to the appointment of administrative committees. Sections shall elect their own officers.

Nominating Committee: The Section Chairman with the advice of the Section Council shall appoint a Committee on Nominations at least fifteen days before each annual meeting. The Section Secretary shall be a member of such Committee.

The names of the members of the Committee on Nominations shall be announced at the first meeting of the Section, at each annual meeting of the Association. The Committee on Nominations shall present at the second meeting of the Section a list of nominees for

the Section offices, and for membership in the Section Council; provided that if the name of any Fellow be transmitted to the Nominating Committee over the signature of ten Fellows of the Section prior to the second meeting of the Section, the Nominating Committee shall add the name of such Fellow to its own list of nominees.

A. *Officers* of each Section shall be a Chairman, a Vice-Chairman, and a Secretary. The Chairman, Vice-Chairman, and Secretary shall be the representatives of the Section to the Governing Council of the Association.

B. *Terms:* New terms begin and old terms expire at the end of annual meetings. After five consecutive years in any elective Section office, except that of Secretary, a member shall be ineligible to reëlection to that office during one Association year.

C. *The Chairman* shall preside at meetings of the Section.

D. *The Vice-Chairman* shall preside at meetings of the Section in the absence of the Chairman.

E. *The Secretary* of the Section shall prepare the scientific program of the Section for the annual meeting, subject to the recommendations of the Section Council, and he shall submit same to the Committee on Meetings and Publications and shall keep the minutes, and other records of the Section, and shall transmit to the Secretary of the Association a copy of the minutes of both business and scientific sessions as soon as practicable thereafter. When unable to be present at meetings, he shall thoroughly instruct a substitute as far in advance of the meeting as possible.

F. *Section Council:* There shall be a Section Council composed of the three officers of the Section and five members, who shall be Fellows of the Section.

Terms of members of the Section Council shall be five years each. In the beginning one shall serve for one year, one for two, one for three, one for four, and one for five years.

Duties of the Section Council shall be:

1. To recommend papers, and to make general recommendations in relation to the annual meeting program.
2. To advise on Section membership.
3. To advise on Section policies.
4. To submit annually to the Governing Council through the Executive Board a report of the transactions of the Section.
5. To report annually to the Governing Council through the Executive Board on the plans, scope and policy of the Section during the succeeding year.
6. To formulate rules of procedure for the Section.
7. To approve and transmit to the Governing Council resolutions originating in the Section.
8. To advise on the publication of papers and reports presented at the Section meetings.
9. To advise with respect to the appointment of technical committees, sub-committees or Section representatives on committees of the Association.

ARTICLE VIII FINANCES

All remittances to the Association shall be deposited to the account of the Treasurer. The Treasurer shall be custodian of investments of the Association and shall disburse funds in accordance with duly authorized vouchers. With the approval of the Executive Board he may establish a drawing account for the Executive Secretary, who shall send to members of the Executive Board a financial summary of receipts and disbursements each month. Once each month, or oftener if called for, he shall also forward to the Treasurer and President an itemized statement of all expenditures. The Executive Secretary and the Treasurer shall be bonded at the expense of the Association in an amount to be determined by the Executive Board. The books of the Association shall be audited annually by certified public accountants, to be appointed by the Executive Board.

ARTICLE IX AMENDMENTS

These By-laws may be amended by a two-thirds vote of those voting on the Governing Council during the annual meeting, provided that twenty-four hours prior written notice thereof has been given. The By-laws may further be amended by a two-thirds vote of those voting at any meeting of the Governing Council called for the purpose, provided that notice thereof shall have been given at least fifteen days prior to such meeting.

THE AMERICAN PUBLIC HEALTH ASSOCIATION

50 West 50th Street, New York, N. Y.

GOVERNING COUNCIL

OFFICERS 1935–1936

President, Walter H. Brown, M.D., Palo Alto, Calif.
President-elect, Thomas Parran, Jr., M.D., Albany, N. Y.
First Vice-President, Robert E. Wodehouse, M.D., Ottawa, Ont., Can.
Second Vice-President, Professor Samuel C. Prescott, Cambridge, Mass.
Third Vice-President, Angel de la Garza Brito, M.D., Mexico City, Mex.
Treasurer, Louis I. Dublin, Ph.D., New York, N. Y.
Executive Secretary, Reginald M. Atwater, M.D., New York, N. Y.
Chairman of Executive Board, John A. Ferrell, M.D., New York, N. Y.

ELECTIVE COUNCILORS

Terms Expiring 1936

Walter H. Brown, M.D., Palo Alto, Calif.
Samuel J. Crumbine, M.D., New York, N. Y.
A. J. Douglas, M.D., Winnipeg, Man., Can.
Allen W. Freeman, M.D., Baltimore, Md.
Wade H. Frost, M.D., Baltimore, Md.
Thomas Parran, Jr., M.D., Albany, N. Y.
Philip S. Platt, Ph.D., Honolulu, T. H.
Milton J. Rosenau, M.D., Chapel Hill, N. C.
Henry F. Vaughan, Dr.P.H., Detroit, Mich.
C.-E. A. Winslow, Dr.P.H., New Haven, Conn.

Terms Expiring 1937

Donald B. Armstrong, M.D., New York, N. Y.
J. Rosslyn Earp, Dr.P.H., Santa Fe, N. M.
J. G. Fitzgerald, Toronto, Ont., Can.
Edward S. Godfrey, Jr., M.D., Albany, N. Y.
Guy S. Millberry, D.D.S., San Francisco, Calif.
Joseph W. Mountin, M.D., Washington, D. C.
William H. Park, M.D., New York, N. Y.
William P. Shepard, M.D., San Francisco, Calif.
Wilson G. Smillie, M.D., Boston, Mass.
John Sundwall, M.D., Ann Arbor, Mich.

Terms Expiring 1938

J. N. Baker, M.D., Montgomery, Ala.
E. L. Bishop, M.D., Knoxville, Tenn.

F. J. Underwood, M.D., Southern Branch

SECTION OFFICERS

Health Officers

Chm., John P. Koehler, M.D., Milwaukee, Wis.
Vice-Chm., William F. Cogswell, M.D., Helena, Mont.
Secy., Huntington Williams, M.D., Baltimore, Md.
Section Council, A. H. Flickwir, M.D., Fort Worth, Tex., Frederick D. Stricker, Portland, Ore., S. Boucher, M.D., Montreal, Can., Leon Banov, M.D., Charleston, S. C., John J. Sippy, M.D., Stockton, Calif.

Laboratory

Chm., Ruth Gilbert, M.D., Albany, N. Y.
Vice-Chm., W. D. Stovall, M.D., Madison, Wis.
Secy., Friend Lee Mickle, Hartford, Conn.

Vital Statistics

Chm., Gaius E. Harmon, M.D., Cleveland, O.
Vice-Chm., Jessamine S. Whitney, New York, N.Y.
Secy., John Collinson, M.D., Washington, D. C.

Public Health Engineering

Chm., Arthur P. Miller, C.E., New York, N. Y.
Vice-Chm., Gordon M. Fair, Cambridge, Mass.
Secy., Roy J. Morton, Nashville, Tenn.

Industrial Hygiene

Chm., Albert S. Gray, M.D., Hartford, Conn.
Vice-Chm., Leverett D. Bristol, M.D., New York, N. Y.
Secy., Bernard S. Coleman, New York, N. Y.

Food and Nutrition

Chm., Fred W. Tanner, Ph.D., Urbana, Ill.
Vice-Chm., Walter S. Frisbie, Washington, D. C.
Secy., Carl R. Fellers, Ph.D., Amherst, Mass.

Child Hygiene

Chm., Geo. T. Palmer, Dr.P.H., New York, N. Y.
Vice-Chm., A. L. Beaghler, M.D., Denver, Colo.
Secy., Don W. Gudakunst, M.D., Detroit, Mich.

Public Health Education

Chm., W. W. Bauer, M.D., Chicago, Ill.
Vice-Chm., Homer N. Calver, New York, N. Y.
Secy., Mary P. Connolly, Detroit, Mich.

Public Health Nursing

Chm., Naomi Deutsch, R.N., Berkeley, Calif.
Vice-Chm., Mary J. Dunn, R.N., Nashville, Tenn.
Secy., Marguerite A. Wales, R.N., New York, N.Y.

Epidemiology

Chm., Kenneth F. Maxcy, M.D., University, Va.
Vice-Chm., M. E. Barnes, M.D., Iowa City, Iowa
Secy., Clarence L. Scamman, M.D., New York, N. Y.

Executive Board

Chairman, John A. Ferrell, M.D., New York, N. Y. *(1936)*
J. N. Baker, M.D., Montgomery, Ala. *(1936)*
John P. Koehler, M.D., Milwaukee, Wis. *(1937)*
Friend Lee Mickle, Hartford, Conn. *(1937)*
John L. Rice, M.D., New York, N. Y. *(1938)*
Huntington Williams, M.D., Baltimore, Md. *(1938)*
Walter H. Brown, M.D., Palo Alto, Calif. *(President)*
Thomas Parran, Jr., M.D., Albany, N. Y. *(President-elect)*
Louis I. Dublin, Ph.D., New York, N. Y. *(Treasurer)*

PAST PRESIDENTS

*Stephen Smith, M.D.	1872, 1873, 1874

* Post-Convention Meeting, Mexico City, Mex., 1930.

RECIPIENTS OF THE SEDGWICK MEMORIAL MEDAL

1929 Charles V. Chapin, M.D.
1930 Theobald Smith, M.D.*
1931 George W. McCoy, M.D.
1932 William H. Park, M.D.
1933 Milton J. Rosenau, M.D.
1934 Professor Edwin O. Jordan
1935 Haven Emerson, M.D.

* Deceased.

SECTION COUNCILS

Health Officers Section
(Organized 1908)

John P. Koehler, M.D., *Chairman*, Commissioner of Health, Milwaukee, Wis.
William F. Cogswell, M.D., *Vice-Chairman*, Department of Public Health, Helena, Mont.
Huntington Williams, M.D., *Secretary*, Commissioner of Health, Baltimore, Md.
A. H. Flickwir, M.D. (1940)
Frederick D. Stricker, M.D. (1939)
S. Boucher, M.D. (1938)
Leon Banov, M.D. (1937)
John J. Sippy, M.D. (1936)

Laboratory Section
(Organized 1899)

Ruth Gilbert, M.D., *Chairman*, State Department of Health, Albany, N. Y.
W. D. Stovall, M.D., *Vice-Chairman*, State Hygienic Laboratory, Madison, Wis.
Friend Lee Mickle, *Secretary*, State Department of Health Laboratories, Hartford, Conn.
W. H. Kellogg, M.D. (1940)
Robert S. Breed, Ph.D. (1939)
Anna W. Williams, M.D. (1938)
M. H. McCrady (1937)
J. V. Mulcahy (1936)

Vital Statistics Section
(Organized 1908)

Gauis E. Harmon, M.D., *Chairman*, Western Reserve University, Cleveland, Ohio
Jessamine S. Whitney, *Vice-Chairman*, 50 West 50th Street, New York, N. Y.
John Collinson, M.D., *Secretary*, Bureau of the Census, Washington, D. C.
A. W. Hedrich, Sc.D. (1940)
W. Thurber Fales, Sc.D. (1939)
Butler Toombs (1938)
John O. Spain (1937)
George H. Van Buren (1936)

Public Health Engineering Section
(Organized 1911)

Arthur P. Miller, C.E., *Chairman*, U. S. Public Health Service, Sub-Treasury Bldg., New York, N. Y.
Gordon M. Fair, *Vice-Chairman*, Harvard University, Cambridge, Mass.
Roy J. Morton, *Secretary*, State Department of Health, Nashville, Tenn.
Warren J. Scott (1940)
C. A. Holmquist (1939)
Richard Messer (1938)
George W. Putnam (1937)
V. M. Ehlers (1936)

Industrial Hygiene Section
(Organized 1914)

Albert S. Gray, M.D., *Chairman*, State Department of Health, Hartford, Conn.
Leverett D. Bristol, M.D., *Vice-Chairman*, 195 Broadway, New York, N. Y.
Bernard S. Coleman, *Secretary*, 386 Fourth Avenue, New York, N. Y.
Henry H. Kessler, M.D. (1940)
R. R. Sayers, M.D. (1939)
Louis Schwartz, M.D. (1938)
Frederick B. Flinn, Ph.D. (1937)
Alice Hamilton, M.D. (1936)

Food and Nutrition Section
(Organized 1917)

Fred W. Tanner, Ph.D., *Chairman*, University of Illinois, Urbana, Ill.
Walter S. Frisbie, *Vice-Chairman*, U. S. Food and Drug Administration, Washington, D. C.
Carl R. Fellers, Ph.D., *Secretary*, Massachusetts State College, Amherst, Mass.
D. Breese Jones, Ph.D. (1940)
Walter H. Eddy, Ph.D. (1939)
J. P. Bushong, D.V.M. (1938)
James A. Tobey, Dr.P.H. (1937)
F. C. Blanck, Ph.D. (1936)

Child Hygiene Section
(Organized 1921)

George T. Palmer, M.D., *Chairman*, Department of Health, New York, N. Y.
A. L. Beaghler, M.D., *Vice-Chairman*, 414 Fourteenth St., Denver, Colo.
Don W. Gudakunst, M.D., *Secretary*, Department of Health, Detroit, Mich.
George P. Barth, M.D. (1940)
Estella F. Warner, M.D. (1939)
Guy S. Millberry, M.D. (1938)
Elizabeth Gardiner, M.D. (1937)
Murray P. Horwood (1936)

Public Health Education Section
(Organized 1922)

W. W. Bauer, M.D., *Chairman*, 535 N. Dearborn Street, Chicago, Ill.
Homer N. Calver, *Vice-Chairman*, 50 West 50th Street, New York, N. Y.
Mary P. Connolly, *Secretary*, 3919 John R Street, Detroit, Mich.
Marjorie Delavan (1940)

William P. Shepard, M.D. (1939)
Evart G. Routzahn (1938)
Ira V. Hiscock (1937)
C. E. Turner (1936)

PUBLIC HEALTH NURSING SECTION
(Organized 1923)

Naomi Deutsch, R.N., *Chairman*, U. S. Public Health Service, Washington, D. C.
Mary J. Dunn, *Vice-Chairman*, Vanderbilt University, Nashville, Tenn.
Marguerite A. Wales, R.N., *Secretary*, 99 Park Avenue, New York, N. Y.
Pearl McIver, R.N. (1940)
Marion W. Sheahan (1939)
Anna Heisler, R.N. (1938)
Ruth Houlton, R.N. (1937)
Amelia Grant, R.N. (1936)

EPIDEMIOLOGY SECTION
(Organized 1929)

Kenneth F. Maxcy, M.D., *Chairman*, University of Virginia, University, Va.
M. E. Barnes, M.D., *Vice-Chairman*, University of Iowa, Iowa City, Ia.
Clarence L. Scamman, M.D., *Secretary*, Commonwealth Fund, New York, N. Y.
J. A. Doull, M.D., (1940)
James P. Leake, M.D. (1939)
C. D. Barrett, M.D. (1938)
Haven Emerson, M.D. (1937)
Alton S. Pope, M.D. (1936)

ASSOCIATE EDITORS OF THE JOURNAL

HENRY F. VAUGHAN, Dr.P.H., Health Officers
JOHN F. NORTON, Ph.D., Laboratory

A. W. Hedrich, Sc.D., *Chairman,* State Dept. of Health, Baltimore, Md.
Gordon M. Fair
E. S. Godfrey, Jr., M.D.
Don M. Griswold, M.D.
Frederick Lee, Ph.D.

* Not a member of the A.P.H.A.

Sub-Committee on Newer Aspects of Amebic Dysentery

George W. McCoy, M.D., *Chairman,* National Institute of Health, Washington, D. C.
Joel I. Connolly
W. F. Draper, M.D.
Arthur E. Gorman
George H. Ramsey, M.D.
W. D. Stovall, M.D.

Sub-Committee on Standard Methods for the Examination of Dishwashing Devices

Major A. Parker Hitchens, *Chairman,* Army Medical Center, Washington, D. C.
Leon Banov, M.D.
Joel I. Connolly
Lieutenant-Colonel James G. Cumming, M.D.
George C. Ruhland, M.D.
R. V. Stone, D.V.M.

Sub-Committee on Communicable Disease Control

Haven Emerson, M.D., *Chairman,* 630 West 168th Street, New York, N. Y.
Leon Banov, M.D.
J. A. Doull, M.D.
Adrian R. Foley, M.D.
Donald T. Fraser, M.B.
John E. Gordon, M.D., Ph.D.
James P. Leake, M.D.
Alton S. Pope, M.D.
Louis W. Sauer, M.D., Ph.D.
Adolph Weinzirl, M.D.
Prof. C.-E. A. Winslow

Sub-Committee on Soil Pollution

H. E. Miller, *Chairman,* U. S. Public Health Service, Washington, D. C.
Charles F. Craig, M.D.
F. Clarke Dugan, C.E.
V. M. Ehlers
Leo F. Ey
James G. McAlpine, Ph.D.

Committee on Professional Education

W. S. Leathers, M.D., *Chairman,* School of Medicine, Vanderbilt University, Nashville, Tenn. (1937)
E. L. Bishop, M.D. (1940)
John Sundwall, M.D. (1940)
Allen W. Freeman, M.D. (1939)
Ralph E. Tarbett, C.E. (1939)
Stanley H. Osborn, M.D. (1938)
Clarence L. Scamman, M.D. (1938)
Henry F. Vaughan, Dr.P.H. (1937)
Lillian A. Hudson, R.N. (1936)
Wilson G. Smillie, M.D. (1936)
William P. Shepard, M.D., *Consultant*
Reginald M. Atwater, M.D. (ex-officio)
Isabel B. Landy, *Secretary,* 50 West 50th Street, New York, N. Y.

Editorial Committee

Henry F. Vaughan, Dr.P.H., *Chairman,* Commissioner of Health, Detroit, Mich.
Allen W. Freeman, M.D.
Clarence L. Scamman, M.D.

Sub-Committee on the Educational Qualifications of Public Health Engineers and Sanitary Inspectors

Ralph E. Tarbett, C.E., *Chairman,* U. S. Public Health Service, Washington, D. C.
J. L. Barron, C.E.
Earnest Boyce, C.E.
Prof. Charles G. Hyde
Arthur P. Miller, C.E.

Sub-Committee on the Educational Qualifications of Health Officers

Allen W. Freeman, M.D., *Chairman,* Johns Hopkins University, Baltimore, Md.
Prof. Ira V. Hiscock
Stanley H. Osborn, M.D.
Clarence L. Scamman, M.D.
Wilson G. Smillie, M.D.
Henry F. Vaughan, Dr.P.H.

Sub-Committee on the Educational Qualifications of Health Educators

John Sundwall, M.D., *Chairman,* University of Michigan, Ann Arbor, Mich.

Sub-Committee on Instruction of Undergraduates in Medical Schools

Wilson G. Smillie, M.D., *Chairman*, Harvard University, Cambridge, Mass.
*Alan Gregg, M.D.
Kenneth F. Maxcy, M.D., Dr.P.H.

Sub-Committee on the Educational Qualifications of Public Health Nurses

Lillian A. Hudson, R.N., *Chairman*, Teachers College, Columbia University, New York, N. Y.
Dorothy Carter, R.N.
Clarence L. Scamman, M.D.
Wilson G. Smillie, M.D.

Sub-Committee on the Educational Qualifications of Vital Statisticians

John Sundwall, M.D., *Chairman*, University of Michigan, Ann Arbor, Mich.
Halbert L. Dunn, M.D., Ph.D.
Gaius E. Harmon, M.D.
A. W. Hedrich, Sc.D.
George St. John Perrott

* Not a member of the A.P.H.A.

Committee on Administrative Practice

C.-E. A. Winslow, Dr.P.H., *Chairman*, Yale University, New Haven, Conn. (1937)
Leverett D. Bristol, M.D. (1939)
George T. Palmer, Dr.P.H. (1939)
Marion Sheahan, R.N. (1939)
Michael M. Davis, Ph.D. (1938)
Joseph W. Mountin, M.D. (1938)
W. F. Walker, Dr.P.H. (1938)
E. L. Bishop, M.D. (1937)
Haven Emerson, M.D. (1937)
Grant Fleming, M.D. (1936)
W. S. Rankin, M.D. (1936)
Henry F. Vaughan, Dr.P.H. (1936)
Charles V. Chapin, M.D., Consultant
Leon Banov, M.D.; Robert H. Riley, M.D.; John J. Sippy, M.D. — Representatives from Health Officers Section
Reginald M. Atwater, M.D. (ex-officio)
Abel Wolman, Chairman, Committee on Research and Standards (ex-officio)
Carl E. Buck, Dr.P.H., Field Director, 50 West 50th Street, New York, N. Y.
Cecile Tonnele, Secretary, 50 West 50th Street, New York, N. Y.

Executive Committee

C.-E. A. Winslow, Dr.P.H., *Chairman*, Yale University, New Haven, Conn.
Haven Emerson, M.D.
George T. Palmer, Dr.P.H.
W. F. Walker, Dr.P.H.
Leon Banov, M.D.; William H. Enneis, M.D.; James Roberts, M.D.; I. F. Thompson, M.D. — Representatives from Health Officers Section

Sub-Committee on Appraisal of City Health Work

George T. Palmer, Dr.P.H., *Chairman*, Department of Health, New York, N. Y.
Earle G. Brown, M.D.
Joel I. Connolly
Grant Fleming, M.D.
Allen W. Freeman, M.D.
Harold H. Mitchell, M.D.
Frank J. Osborne
Grace Ross, R.N.
John J. Sippy, M.D.
Henry F. Vaughan, Dr.P.H.
W. F. Walker, Dr.P.H.

Sub-Committee on Public Health Nursing

Marion Sheahan, R.N., *Chairman*, Director, Division of Public Health Nursing, State Department of Health, Albany, N. Y.
Carl E. Buck, Dr.P.H.
Marion Douglas, R.N.
Amelia Grant, R.N.
Theresa K. Guthrie, R.N.
Alma Haupt, R.N.
Hortense Hilbert, R.N.
Pearl McIver, R.N.
Agnes Martin, R.N.
Sophie C. Nelson, R.N.
Olivia Peterson, R.N.
Marian G. Randall
W. F. Walker, Dr.P.H.

Sub-Committee on Rural Health Work

E. L. Bishop, M.D., *Chairman,* Tennessee Valley Authority, Knoxville, Tenn.
J. N. Baker, M.D.
James B. Black, M.D.
Henry D. Chadwick, M.D.
Grant Fleming, M.D.
Allen W. Freeman, M.D.
Edward S. Godfrey, Jr., M.D.
H. A. Kroeze
W. S. Leathers, M.D.
Alphonse Lessard, M.D.
William A. McIntosh, M.D.
Joseph W. Mountin, M.D.
Marion Sheahan, R.N.
John J. Sippy, M.D.
W. F. Walker, Dr.P.H.
C. E. Waller, M.D.
W. W. Bauer, M.D., Consultant

Sub-Committee on Health Conservation Contest

Henry F. Vaughan, Dr.P.H., *Chairman,* Commissioner of Health, Detroit, Mich.
R. G. Beachley, M.D.
Herman N. Bundesen, M.D.
A. J. Chesley, M.D.
T. F. Cunneen
George B. Darling, Dr.P.H.
Louis I. Dublin, Ph.D.
Grant Fleming, M.D.
Allen W. Freeman, M.D.
A. T. McCormack, M.D.
Joseph W. Mountin, M.D.
Frank J. Osborne
W. S. Rankin, M.D.
John L. Rice, M.D.
George C. Ruhland, M.D.
John J. Sippy, M.D.
W. F. Walker, Dr.P.H.

Sub-Committee on Current Practices of Health Departments

Joseph W. Mountin, M.D., *Chairman,* U. S. Public Health Service, Washington, D. C.
E. L. Bishop, M.D.
Mayhew Derryberry, Ph.D.
Allen W. Freeman, M.D.
George T. Palmer, Dr.P.H.
John L. Rice, M.D.
Henry F. Vaughan, Dr.P.H.
W. F. Walker, Dr.P.H.

Sub-Committee on Evaluation of Administrative Practices

Haven Emerson, M.D., *Chairman,* Columbia University, 630 West 168th Street, New York, N. Y.
Allen W. Freeman, M.D.
Don M. Griswold, M.D.
Frank L. Kelly, M.D.
Joseph W. Mountin, M.D.
John L. Rice, M.D.
Henry F. Vaughan, Dr.P.H.
W. F. Walker, Dr.P.H.

Diphtheria
Donald Fraser, M.B., D.P.H.
E. S. Godfrey, Jr., M.D., referee
W. T. Harrison, M.D.
G. F. McGinnes, M.D.
William H. Park, M.D.
V. K. Volk, M.D.

Measles
J. P. Leake, M.D., referee
A. G. Silverman, M.D.
F. H. Top, M.D., C.P.H., Secretary

Scarlet Fever
Gaylord W. Anderson, M.D., Secretary
J. P. Koehler, M.D.
G. H. Ramsey, M.D.
M. V. Veldee, M.D., referee

Whooping Cough
G. H. Becker, M.D.
F. L. Kelly, M.D.
P. L. Kendrick, Sc.D., Secretary
Thomas M. Rivers, M.D., referee

Typhoid Carriers
Gaylord W. Anderson, M.D.
A. J. Chesley, M.D.
F. C. Forsbeck, M.D.
Don M. Griswold, M.D., referee
A. V. Hardy, M.D.

Sub-Committee on Industrial Health Appraisal

Leverett D. Bristol, M.D., *Chairman,* American Telephone and Telegraph Company, 195 Broadway, New York, N. Y.
G. H. Gehrmann, M.D.
Merle Hale
Violet Hodgson
A. J. Lanza, M.D.
Sophie C. Nelson, R.N.
George T. Palmer, Dr.P.H.
W. A. Sawyer, M.D.
E. L. Simonds
J. W. Towsen
W. F. Walker, Dr.P.H.

Association Committees

Nominating Committee

John P. Koehler, M.D., *Chairman*, Commissioner of Health, Milwaukee, Wis.
Robert S. Breed, Ph.D., Laboratory Section
Mary P. Connolly, Public Health Education Section
Robert D. Defries, M.D., Epidemiology Section
E. L. Filby, Public Health Engineering Section
Alma C. Haupt, R.N., Public Health Nursing Section
Professor Samuel C. Prescott, Food and Nutrition Section
George C. Ruhland, M.D., Health Officers Section
Henry F. Smyth, M.D., Industrial Hygiene Section
Stewart G. Thompson, D.P.H., Vital Statistics Section
LeRoy A. Wilkes, M.D., Child Hygiene Section

Sedgwick Memorial Medal Committee

George W. McCoy, M.D., *Chairman*, National Institute of Health, Washington, D. C. (1936)
William H. Park, M.D. (1937)
Milton J. Rosenau, M.D. (1937)
Donald B. Armstrong, M.D. (1936)
Haven Emerson, M.D. (1936)
Edwin O. Jordan, Ph.D. (1936)
Karl F. Meyer, Ph.D. (1936)

Committee on American Museum of Hygiene

Victor G. Heiser, M.D., *Chairman*, 49 West 49th Street, New York, N. Y.
Homer N. Calver, *Secretary*, 50 West 50th Street, New York, N. Y.
Bertrand Brown
Louis I. Dublin, Ph.D.
Sally Lucas Jean
Guy S. Millberry, D.D.S.
Evart G. Routzahn
C.-E. A. Winslow, Dr.P.H.

Committee on Autopsies

Haven Emerson, M.D., *Chairman*, 630 West 168th Street, New York, N. Y.
Major George H. Dunham
W. Thurber Fales, Sc.D.

Committee on Constitution and By-Laws

Henry F. Vaughan, Dr.P.H., *Chairman*, Commissioner of Health, Detroit, Mich.
Haven Emerson, M.D.
W. S. Rankin, M.D.

Committee to Study Possibility of Forming Mental Hygiene Section

Haven Emerson, M.D., *Chairman*, 630 West 168th Street, New York, N. Y.

Section Committees

Laboratory Section

Coördinating Committee on Standard Methods (allocated to Committee on Research and Standards)

A. P. Hitchens, M.D., *Chairman*, Army Medical Center, Walter Reed Hospital, Washington, D. C.
Robert S. Breed, Ph.D.
John F. Norton, Ph.D.
W. D. Stovall, M.D.
Friend Lee Mickle, ex-officio, Secretary

Standard Methods Committee on Diagnostic Procedures and Reagents

W. D. Stovall, M.D., *Chairman*, State Laboratory of Hygiene, Madison, Wis.
Referee for:
Amebiasis—Bertha Kaplan Spector, M.D., U. S. Public Health Service, Chicago, Ill.
Diphtheria Virulence Tests—D. T. Fraser, M.B., Dept. of Hygiene, Univ. of Toronto, Toronto, Ont., Canada
Gonorrhea and the Gonococcus—Charles M. Carpenter, M.D., University of Rochester, Rochester, N. Y.
Laboratory Diagnostic Procedures in the Recognition of Various Food Poisonings—S. A. Koser, Ph.D., University of Chicago, Chicago, Ill.
Meningitis and Meningococcus—Sara E. Branham, M.D., Ph.D., National Institute of Health, Washington, D. C.
Recognition and Significance of Hemolytic Streptococci in Infectious Diseases—Julia M. Coffey, Division of Laboratories and Research, State Dept. of Health, Albany, N. Y.
Serological and Bacteriological Procedures in the Diagnosis of Enteric Fevers—

Marion B. Coleman, Division of Laboratories and Research, State Dept. of Health, Albany, N. Y.
Serological, Bacteriological and Other Biological Procedures in the Diagnosis of Undulant Fever—G. D. Cummings, Ph.D., Bureau of Laboratories, State Dept. of Health, Lansing, Mich.
Serological Tests for the Diagnosis of Syphilis—Ruth Gilbert, M.D., Division of Laboratories and Research, State Dept. of Health, Albany, N. Y.
Standard Tests for the Recognition of Pneumococcic Types Associated with Pneumonia—Georgia M. Cooper, State Board of Health, Raleigh, N. C.
Studies on the Toxicity of Dyes for Bacteria—Edmund K. Kline, D.P.H., Cattaraugus County Dept. of Health, Olean, N. Y.
Tularemia and Bacterium Tularense—J. G. McAlpine, Ph.D., Director, State Laboratories, Montgomery, Ala.
Tuberculosis and the Tubercle Bacillus—A. L. MacNabb, D.V.M., Bureau of Laboratories, Dept. of Health, Toronto, Ont., Canada
Typhus Fever and Laboratory Methods for Its Recognition—Henry Welch, Ph.D., 247 Pearl St., Hartford, Conn.
Whooping Cough and B. Pertussis—Pearl Kendrick, Sc.D., Bureau of Laboratories, State Dept. of Health, Grand Rapids, Mich.

Associate Referee for:
Tuberculosis and the Tubercle Bacillus—M. H. Brown, M.D., Toronto, Canada
Tularemia and Bacterium Tularense—George Brigham, Ph.D., U. S. Quarantine Station, Mobile, Ala.
Whooping Cough and B. Pertussis—J. J. Miller, M.D., 384 Post St., San Francisco, Calif., and George McL. Lawson, M.D., 101 W. Chestnut St., Louisville, Ky.

Standard Methods Committee on Examination of Water and Sewage

John F. Norton, Ph.D., *Chairman*, The Upjohn Company, Kalamazoo, Mich.

Referee for:
Bacteriological Methods for Water—Mac H. McCrady, 89 Notre Dame East, Montreal, Que., Canada
Biochemical Oxygen Demand Methods—F. E. Daniels, Dept. of Health, Harrisburg, Pa.
Chemical Methods for Water—A. M. Buswell, Ph.D., University of Illinois, Urbana, Ill., and S. T. Powell, 330 N. Charles St., Baltimore, Md.
Chemical Methods of Sewage—F. Wellington Gilcreas, State Department of Health, Albany, N. Y.
Microscopic Methods of Water and Sewage—Theodore A. Olsen, Division of Sanitation, State Board of Health, Minneapolis, Minn.
Swimming Pools and Bathing Place Waters—W. L. Mallmann, Ph.D., Dept. of Bacteriology and Hygiene, Michigan State College, East Lansing, Mich., and M. S. Nichols, Ph.D., State Department of Health, Madison, Wis.

Standard Methods Committee on Examination of Dairy and Food Products

Robert S. Breed, Ph.D., *Chairman*, Box 299, Geneva, N. Y.

Referee for:
Chemical Methods of Examining Dairy Products—F. C. Blanck, Ph.D., Bureau of Chemistry and Soils, Washington, D. C.
Methods of Counting Bacteria in Dairy Products—A. H. Robertson, Ph.D., State Department of Agriculture and Markets, Albany, N. Y.
Methods of Detecting Specific Types of Bacteria in Dairy Products—Mac H. McCrady, 89 Notre Dame East, Montreal, Que., Canada
Shellfish Examinations—C. A. Perry, Sc.D., Bureau of Bacteriology, State Dept. of Health, Baltimore, Md.
Laboratory Equipment—R. V. Stone, D.V.M., County Health Department, Los Angeles, Calif.
Methods for Detecting Organisms of Colon Group—A. J. Slack, M.D., Institute of Public Health, London, Ontario, Canada

Associate Referee for:
Bacteriological Methods of Examining Ice Cream—F. W. Fabian, Ph.D., Michigan State College, East Lansing, Mich.
Methods of Examining Milk for Evidences of Brucella Infection—I. Forrest Huddleson, Ph.D., Michigan State College, Lansing, Mich.
Methods of Examining Milk for Tubercle Bacilli—W. A. Hagan, D.V.M., New York State Veterinary College, Cornell University, Ithaca, N. Y.
Methods of Identifying Streptococci in Dairy Products—G. J. Hucker, Ph.D., Box 299, Geneva, N. Y.
Methylene Blue Reductase Test—H. R. Thornton, Ph.D., Dept. of Dairying, University of Alberta, Edmonton, Alta.

Microbiological Methods for Examining Butter—E. H. Parfitt, Dairy Dept., Purdue Univ., Lafayette, Ind.
Milk Sediment Test—Caryl C. Carson, 166 Freeman St., Hartford, Conn.
Utilization of Milk and Digested Milk in Standard Agar Media—C. S. Mudge, University of California, Davis, Calif.

Committee on Milk Pasteurization Studies (allocated to Committee on Research and Standards)

George J. Hucker, Ph.D., *Chairman*, Box 299, Geneva, N. Y.
Robert S. Breed, Ph.D.
L. H. Burgwald
Mac H. McCrady
R. P. Myers, Ph.D.
Robert C. Thomas

Committee on Progress in and Present Status of Biological Products (allocated to Committee on Research and Standards)

William H. Park, M.D., *Chairman*, Foot of East 16th Street, New York, N. Y.
Donald T. Fraser, M.B.
George W. McCoy, M.D.
Elliott S. A. Robinson, M.D., Ph.D.
A. B. Wadsworth, M.D.

Committee on Advisability of Laboratory Examination of Food Handlers (allocated to Committee on Research and Standards)

Minna Crooks Young, *Chairman*, State Department of Health, Lansing, Mich.
Ruth Gilbert, M.D.
S. A. Koser, Ph.D.
A. L. MacNabb, D.V.M.
Friend Lee Mickle
Mazÿck P. Ravenel, M.D.

Committee on Waterways Pollution Studies (to coöperate with Committee on Waterways Pollution of Public Health Engineering Section)

James A. Newlands, *Chairman*, 11 Laurel Street, Hartford, Conn.
E. J. Theriault

Committee on Section Representation on the Governing Council (unallocated)

Friend Lee Mickle, *Chairman*, Box 1139, Hartford, Conn.
Robert S. Breed, Ph.D.
Ruth Gilbert, M.D.
W. H. Kellogg, M.D.
Mazÿck P. Ravenel, M.D.
W. D. Stovall, M.D.

Committee on Scientific Exhibits (allocated to Committee on Meetings and Publications)

Fred O. Tonney, M.D., *Chairman*, City Board of Health, Chicago, Ill.
W. D. Dotterer
Ruth Gilbert, M.D.
A. Parker Hitchens, M.D.
A. L. MacNabb, D.V.M.

Committee on Aspects of Veterinary Public Health (allocated to Committee on Meetings and Publications)

R. V. Stone, D.V.M., *Chairman*, Hall of Justice, Los Angeles, Calif.
William A. Hagan, D.V.M.
John G. Hardenbergh, D.V.M.
A. L. MacNabb, D.V.M.
I. A. Merchant, D.V.S.

Laboratory Section Representative on the Commission for the Study of Biological Stains

W. D. Stovall, M.D., State Laboratory of Hygiene, Madison, Wis.

Vital Statistics Section

Committee on Accident Statistics (allocated to Committee on Administrative Practice)

Robert J. Vane, *Acting Chairman*, Metropolitan Life Insurance Company, 1 Madison Avenue, New York, N. Y.
Earle G. Brown, M.D.
J. V. DePorte, Ph.D.
W. Thurber Fales, Sc.D.
T. F. Murphy, M.D.
Irva C. Plummer
George H. Van Buren
*R. L. Forney (Consultant)

Committee to Revise the Rules of Statistical Practice (allocated to Committee on Administrative Practice)

Timothy F. Murphy, M.D., *Chairman*, Bureau of Census, Washington, D. C.
Halbert L. Dunn, M.D., Ph.D.
J. V. DePorte, Ph.D.

* Not a member of A.P.H.A.

Committee on Forms and Methods of Statistical Practice (allocated to Committee on Administrative Practice)

A. W. Hedrich, Sc.D., *Chairman,* State Department of Health, Baltimore, Md.
Selwyn D. Collins, Ph.D.
John Collinson, M.D., Dr.P.H.
*Sheldon L. Howard
L. W. Hutchcroft
Timothy F. Murphy, M.D.
Elizabeth Parkhurst

Committee on Registration of Births out of Wedlock (allocated to Committee on Administrative Practice)

J. V. DePorte, Ph.D., *Chairman,* State Department of Health, Albany, N. Y.
W. Thurber Fales, Sc.D.
*Sybil Foster
*Agnes K. Hanna
L. W. Hutchcroft

Committee on Death Certification (allocated to Committee on Administrative Practice)

Marjorie T. Bellows, *Chairman,* Department of Health, Westchester County, White Plains, New York
Haven Emerson, M.D.
Matthias Nicoll, Jr., M.D.
The members of the Vital Statistics Section Council

Committee on Exhibits (allocated to Committee on Meetings and Publications)

John Collinson, M.D., Dr.P.H., *Chairman,* Bureau of the Census, Washington, D. C.

Public Health Engineering Section

Committee on Bathing Places (Joint Committee with Conference of State Sanitary Engineers) (allocated to Committee on Research and Standards)

W. J. Scott, *Chairman,* 947 West Boulevard, Hartford, Conn.
J. L. Barron
W. H. Cary
S. DeM. Gage

Advisers

Epidemiology Section
L. L. Arnold, M.D.
M. J. Rosenau, M.D.

Laboratory Section
W. L. Mallmann, Ph.D.
M. S. Nichols, Ph.D.

Committee on Air Hygiene (allocated to the Committee on Research and Standards)

E. B. Phelps, *Chairman,* 630 West 168th Street, New York, N. Y.
J. I. Connolly
S. DeM. Gage
H. B. Meller
Edward Wright

Advisers

Philip Drinker
F. O. Tonney, M.D.

Committee on Fellowship and Membership (allocated to Committee on Fellowship and Membership)

M. M. Cohn, *Chairman,* City Hall, Schenectady, N. Y.
E. B. Besselievre
G. M. Fair
E. L. Filby
A. H. Fletcher
R. F. Goudey
H. B. Hommon
C. G. Hyde
C. E. Keefer
T. J. Lafreniere
Richard Messer
W. J. Orchard
E. L. Waterman
L. F. Warrick
R. S. Weston

Committee on Industrial Sanitation (unallocated)

C. L. Pool, *Chairman,* Room 335, State Office Bldg., Providence, R. I.
W. Scott Johnson
W. J. Scott

Committee on Milk Supply (Joint Committee with Conference of State Sanitary Engineers) (allocated to Committee on Research and Standards)

C. A. Holmquist, *Chairman,* State Department of Health, Albany, N. Y.
L. C. Frank
H. A. Whittaker

Committee on Municipal Public Health Engineering (unallocated)

W. H. Cary, *Chairman,* Department of Health, Detroit, Mich.
Aime Cousineau
A. H. Fletcher
A. E. Gorman
W. S. Johnson
F. G. Legg
Sol Pincus

* Not a member of A.P.H.A.

Committee on Plumbing (Joint Committee with Conference of State Sanitary Engineers) (allocated to Committee on Research and Standards)

J. I. Connolly, *Chairman*, 704 City Hall, Chicago, Ill.
H. E. Babbitt
W. C. Groeniger
A. E. Hansen
H. N. Old

Committee on Promotion of Environmental Sanitation (allocated to Committee on Research and Standards)

V. M. Ehlers, *Chairman*, Capitol, Austin, Tex.
Earl Devendorf
C. G. Gillespie
H. A. Kroeze
G. O. Pierce
E. D. Rich
Jane H. Rider

Committee on Rural Sanitation (Joint Committee with Conference of State Sanitary Engineers and the American Society of Agricultural Engineers) (allocated to Committee on Research and Standards)

H. E. Miller, *Chairman*, U. S. Public Health Service, Washington, D. C.
L. M. Clarkson
A. C. Decker
M. D. Hollis
L. H. Male
A. H. Wieters

Committee on Scope of Technical Activities (unallocated)

H. A. Whittaker (1936), *Chairman*, State Department of Health, Minneapolis, Minn.
G. M. Fair (1939)
P. S. Fox (1940)
A. E. Gorman (1937)
E. B. Phelps (1938)

Committee on Sewage Disposal (allocated to Committee on Research and Standards)

Langdon Pearse, *Chairman*, P. O. Drawer F, Winnetka, Ill.
C. K. Calvert
H. P. Eddy
C. E. Keefer
F. W. Mohlman
G. G. Nasmith
L. B. Reynolds
Willem Rudolfs
F. M. Veatch
P. J. A. Zeller

Committee on Shellfish (allocated to Committee on Research and Standards)

L. M. Fisher, *Chairman*, U. S. Public Health Service, Washington, D. C.
M. H. Bidwell
S. DeM. Gage
Richard Messer
R. E. Tarbett
Edward Wright

Adviser

C. T. Butterfield

Committee on Summer Camps and Roadside Places Involving Health Hazards

E. D. Rich, *Chairman*, State Health Dept., Lansing, Mich.
C. E. Green
V. B. Lamoureux

Committee on Waterways Pollution (allocated to Committee on Research and Standards)

L. F. Warrick, *Chairman*, Capitol Building, Madison, Wis.
C. M. Baker
Earnest Boyce
Richard Messer
R. M. Harris
F. H. Waring

Advisers

Epidemiology Section
E. O. Jordan, M.D.
M. V. Veldee, M.D.
Laboratory Section
James A. Newlands

Committee on Water Supply (allocated to Committee on Research and Standards)

A. E. Gorman, *Chairman*, 6743 Olympia Ave., Chicago, Ill.
R. D. Bates
H. M. Freeburn
H. S. Hutton
H. E. Jordan
E. G. Eggert

Industrial Hygiene Section

Committee on Industrial Anthrax (allocated to Committee on Research and Standards)

Henry Field Smyth, M.D., Dr.P.H., *Chairman*, University of Pennsylvania, Philadelphia, Pa.
*Volney S. Cheney, M.D.

* Not a member of the A.P.H.A.

Committee on Standard Practices in the Problem of Compensation of Occupational Diseases (allocated to Committee on Research and Standards)

Henry H. Kessler, M.D., *Chairman*, State Dept. of Labor, 31 Lincoln Park, Newark, N. J.
Elizabeth B. Bricker, M.D.
Bernard S. Coleman
Emery R. Hayhurst, M.D.
May R. Mayers, M.D.
George M. Price, M.D.
Eleanor Rantoul
R. R. Sayers, M.D.

Committee on Volatile Solvents (allocated to Committee on Research and Standards)

Henry Field Smyth, M.D., Dr.P.H., *Chairman*, University of Pennsylvania, Philadelphia, Pa.
George H. Gehrmann, M.D.
Alice Hamilton, M.D.
William P. Yant

Committee on Pneumoconiosis (allocated to Committee on Research and Standards)

R. R. Sayers, M.D., *Chairman*, U. S. Public Health Service, Washington, D. C.
Emery R. Hayhurst, M.D.
A. J. Lanza, M.D.
Adelaide R. Smith, M.D.

Committee on Lead Poisoning (allocated to Committee on Research and Standards)

Albert S. Gray, M.D., *Chairman*, State Department of Health, Hartford, Conn.
Joseph Aub, M.D.
G. H. Gehrmann, M.D.

Officers—President, I. C. Riggin, M.D.; First Vice-President, C. J. Vaughn, M.D.; Second Vice-President, Frances Montgomery, R.N.; Third Vice-President, M. Z. Bair; Secretary-Treasurer, G. Foard McGinnes, M.D.

Meetings: 1st Annual Meeting—Birmingham, Ala.—November 14–16, 1932; 2nd Annual Meeting, Richmond, Va.—November 13, 1933; 3rd Annual Meeting, San Antonio, Tex.—November 12–14, 1934; 4th Annual Meeting—St. Louis, Mo.—November 19–20, 1935; 5th Annual Meeting—Baltimore, Md.—November, 1936.

Resolutions

THE Chairman of the Resolutions Committee, John A. Ferrell, M.D., read the following resolutions, which were unanimously adopted by the Governing Council, October 9, 1935.

I. IN MEMORIAM

RESOLVED, that it is with a sense of irreparable loss that the American Public Health Association records the deaths, since our last Annual Meeting, of the following fifty members and Fellows:

H. L. Abramson, M.D., St. John, N. B., Canada. Elected Member 1919
H. L. Akridge, M.D., Brunswick, Ga. Elected Member 1923, Fellow 1929
Lemar W. Andrews, M.D., Warsaw, N. Y. Elected Member 1919
C. A. Bevan, M.D., West Haven, Conn. Elected Member 1918, Fellow 1923
George H. Bigelow, M.D., Boston, Mass. Elected Member 1923, Fellow 1929
Dr. John H. Blanks, Zion, Ill. Elected Member 1925
J. A. Chevigny, M.D., Hammond, Ind. Elected Member 1931
Marguerite J. Clancy, R.N., Asbury Park, N. J. Elected Member 1926
E. Linwood Cornman, V.M.D., Marietta, Pa. Elected Member 1926
Henry A. Cotton, M.D., Trenton, N. J. Elected Member 1932
Nelson C. Davis, M.D., Bahia, Brazil, S. A. Elected Member 1923
F. F. DeVore, M.D., Toledo, O. Elected Member 1927
C. St. Clair Drake, M.D., Jacksonville, Ill. Elected Member 1914
Francis C. Driscoll, A.B., Quincy, Mass. Elected Member 1934
Carroll W. Eddy, D.V.M., Cleveland, O. Elected Member 1926
M. Frances Etchberger, Baltimore, Md. Elected Member 1931
Harry F. Ferguson, Springfield, Ill. Elected Member 1916
Frederick T. Fitch, M.D., East Hampton, Conn. Elected Member 1932
M. B. Harutun, M.D., Joplin, Mo. Elected Member 1920, Fellow 1923
M. O. Heckard, M.D., Chicago, Ill. Elected Member 1907, Fellow 1922
W. G. Hollingworth, D.V.S., Utica, N. Y. Elected Member 1919, Fellow 1926
John C. Humphreys, M.D., Philadelphia, Pa. Elected Member 1926
George W. Hunter, Ph.D., Claremont, Calif. Elected Member 1928
George H. Jennings, M.D., Jewett City, Conn. Elected Member 1916
J. H. Kuser, M.D., San Rafael, Calif. Elected Member 1920
John LeFeber, Milwaukee, Wis. Elected Member 1913
George T. Lennon, Haverhill, Mass. Elected Member 1918
Jorge Le-Roy, M.D., Havana, Cuba. Elected Member 1911, Fellow 1923
Charles W. Many, M.D., Doylestown, Pa. Elected Member 1917
Mae E. Mathers, R.N., Ashland, Va. Elected Member 1934
Lucy Minnigerode, R.N., Washington, D. C. Elected Member 1924
Paul F. Nichols, M.S., Berkeley, Calif. Elected Member 1934
Charles Norris, M.D., New York, N. Y. Elected Member 1920
Herbert C. Ober, M.D., D.M.D., Newton, Mass. Elected Member 1932
Dr. James M. Parrott, Raleigh, N. C. Elected Member 1932
Mrs. William L. Putnam, Boston, Mass. Elected Member 1915
Vernon Robins, M.D., Louisville, Ky. Elected Member 1916, Fellow 1922
Charles V. Roman, M.D., Nashville, Tenn. Elected Member 1926
Mrs. Joseph Sanders, Washington, D. C. Elected Member 1933
Anna M. Scholfield, Providence, R. I. Elected Member 1932
Kathryn Schulken, R.N., Denver, Colo. Elected Member 1931, Fellow 1934
G. H. Sherman, M.D., Detroit, Mich. Elected Member 1918
Sir Clifford Sifton, Toronto, Ont., Canada. Honorary Fellow
Thomas J. Strauch, Richmond, Va. Elected Member 1919
Charles Strauss, New York, N. Y. Elected Member 1914
George R. Thompson, M.D., Luzerne, N. Y. Elected Member 1931
A. Brioso Vasconcelos, M.D., Mexico City,

Mex. Elected Member 1921, Fellow 1923
William H. Wakelee, Southbury, Conn. Elected Member 1933
Henry P. Walcott, M.D., Cambridge, Mass. Honorary Fellow
Prof. John Weinzirl, Seattle, Wash. Elected Member 1906, Fellow 1922

II. ENVIRONMENTAL SANITATION

WHEREAS there exist along the boundary between Mexico and the United States various important health problems, including especially those relating to environmental sanitation, and

WHEREAS the solution of these problems involves the concerted efforts of the public health authorities of both countries and of the states concerned, and

WHEREAS plans for dealing with these problems should be coöperatively formulated and effectively carried out, therefore be it

RESOLVED, that the American Public Health Association is in sympathy with the objectives stated, and that its President is authorized in his discretion to appoint a committee to coöperate with the health authorities, federal, and state, of both countries, in formulating a suitable program and in carrying it out.

III. RESOLUTION TO LOCAL COMMITTEE AND OTHER LOCAL GROUPS

RESOLVED, that the officers and members of the American Public Health Association present at its 64th Annual Meeting in Milwaukee, Wis., express their deep appreciation to the Mayor, the Common Council, the City Departments and the citizenry of Milwaukee for their warm reception and generous hospitality; and be it further

RESOLVED, that the gratitude of the officers and members be extended to Dr. John P. Koehler, Health Commissioner of Milwaukee, and General Chairman of the Local Committee, to every member of his committee, and to all organizations represented thereon, and to the Wisconsin State Board of Health, under the direction of Dr. C. A. Harper, for their many courtesies and efficient helpfulness and generosity in their provisions for this meeting, and be it further

RESOLVED, that the sincere admiration and thanks of the assembled membership be recorded to Dr. John P. Koehler, and to every one of his assistants and helpers for their devoted attention to the planning and conduct of this meeting, which will be long remembered as one of the most successful in the Association's history.

IV. RESOLUTION TO PRESS AND RADIO

RESOLVED, that the American Public Health Association acknowledge its indebtedness to the press and the radio, national, state, and local, for their excellence of service in connection with its 64th Annual Meeting.

V. RESOLUTION TO MILWAUKEE HOTELS

RESOLVED, that the American Public Health Association record its appreciation to the Milwaukee Association of Commerce, the Milwaukee Auditorium, and the Hotel Schroeder and other Milwaukee hotels, for their valuable assistance in the conduct of its 64th Annual Meeting.

VI. RESOLUTION TO EXECUTIVE OFFICE STAFF AND COMMITTEE ON MEETINGS AND PUBLICATIONS

RESOLVED, that the commendation of the officers and the members be recorded to the Executive Office Staff of the American Public Health Association, particularly with reference to the Committee on Meeting and Publications, for efficient service in connection with the 64th Annual Meeting.

The Health Conservation Contests

SINCE 1929 the Chamber of Commerce of the United States with the coöperation of the American Public Health Association has conducted annually a Health Conservation Contest for cities. The success of these competitions was so outstanding that in 1934 a similar Contest for rural areas was inaugurated.

The names of the first award and honorable mention winners in both Contests since their inception are listed below:

1929 City Health Contest Awards *

Group I:
Winning City: Milwaukee, Wis.
Honorable Mention Cities: Detroit, Mich., Philadelphia, Pa., San Francisco, Calif., Brooklyn, N. Y., and Buffalo, N. Y.

Group II:
Winning City: Syracuse, N. Y.
Honorable Mention Cities: New Haven, Conn., Rochester, N. Y., Cincinnati, Ohio, Yonkers, N. Y., and Albany, N. Y.

Group III:
Winning City: East Orange, N. J.
Honorable Mention Cities: Rockford, Ill., Racine, Wis., Pasadena, Calif., Harrisburg, Pa., and Greensboro, N. C.

Group IV:
Winning City: White Plains, N. Y.
Honorable Mention Cities: Cumberland, Md., Alhambra, Calif., Aurora, Ill., Durham, N. C., and Santa Ana, Calif.

Group V:
Winning City, Sidney, Ohio
Honorable Mention Cities: LaSalle, Ill., South Orange, N. J., Eureka, Kans., Palo Alto, Calif., and Natchitoches, La.

1930 City Health Contest Awards †

Group I:
Winning City: Detroit, Mich.
Honorable Mention Cities: Milwaukee, Wis., Philadelphia, Pa., San Francisco, Calif., Baltimore, Md., and Buffalo, N. Y.

Group II:
Winning City: Newark, N. J.
Honorable Mention Cities: Cincinnati, Ohio, Rochester, N. Y., Kansas City, Mo., Denver, Colo., and Memphis, Tenn.

Group III:
Winning City: New Haven, Conn.
Honorable Mention Cities: Syracuse, N. Y., Yonkers, N. Y., Hartford, Conn., Utica, N. Y., and Reading, Pa.

Group IV:
Winning City: Racine, Wis.
Honorable Mention Cities: Harrisburg, Pa., Evanston, Ill., East Orange, N. J., Durham, N. C., and Pasadena, Calif.

Group V:
Winning City: Alhambra, Calif.
Honorable Mention Cities: Salem, Ore., White Plains, N. Y., West Orange, N. J., Watertown, N. Y., and Fargo, N. D.

Group VI:
Winning City: Chestertown, Md.
Honorable Mention Cities: Sidney, Ohio, South Orange, N. J., Albany, Ga., Palo Alto, Calif., and LaSalle, Ill.

1931 City Health Contest Awards †

Group I:
Winning City: Milwaukee, Wis.
Honorable Mention Cities: Baltimore, Md., Detroit, Mich., Philadelphia, Pa., Pittsburgh, Pa., and St. Louis, Mo.

Group II:
Winning City: Rochester, N. Y.
Honorable Mention Cities: Cincinnati, Ohio, Kansas City, Mo., Minneapolis, Minn., Newark, N. J., and Toledo, Ohio

Group III:
Winning City: New Haven, Conn.
Honorable Mention Cities: Grand Rapids, Mich., Hartford, Conn., Syracuse, N. Y., Utica, N. Y., and Yonkers, N. Y.

Group IV:
Winning City: Evanston, Ill.
Honorable Mention Cities: East Orange, N. J., Harrisburg, Pa., Kenosha, Wis., Pasadena, Calif., and Racine, Wis.

The American Museum of Hygiene

YOUR committee is particularly pleased to report the further crystallization of interest in Chicago. Although the local committee organization which was referred to in our report last year did not materialize, definite progress is being made under the leadership of Max Epstein. He has prepared, with the assistance of members of your committee, a preliminary descriptive outline for what is tentatively designated a Center of Health. This very well carries out the concept of the committee for a broad program embracing all phases of health and public health presented through the most modern exhibit and educational devices. This proposal has been favorably received by the Planning Committee of the Chicago Exposition Authority, which group has in hand the creation of a permanent exposition on part of the site of the Century of Progress.

We look forward to the first separate American Museum of Hygiene being a permanent and important unit in that exposition. Former plans for developing a health and medical section of the Museum of Science and Industry in Chicago, using exhibits from the Century of Progress as a nucleus, have been laid aside pending this new development. The desirability of a separate institution has continuously been stressed with interested people in Chicago.

A second development of importance is taking place in New York. In this city, work is already under way in constructing animated exhibits for a new section on hygiene in the American Museum of Natural History. This work is financed by a P.W.A. grant and members of your committee are advising with those responsible for this section. We have also made available to them the complete files of information which the committee has assembled. Although the present plans for this section fall short of the complete program which was proposed to the Museum of Natural History in 1930 by the secretary of your committee, it is a progressive step in health education. As such, it may serve to stimulate interest in the eventual establishment in New York City of a Museum of Hygiene adequate to the opportunities which this great city offers.

A third development of considerable interest has occurred on the West Coast. During the year the Western Branch of the American Public Health Association created a Committee on Health Education Exhibit Material. The studies of that committee have led it to conclude that the Western Branch may well become active and undertake a continuous program in this field. It believes particularly that "an unusual opportunity exists for the presentation of an outstanding exhibit or museum on public health at the International Exposition to be held in the San Francisco Bay area in 1938." A resolution was adopted by the Western Branch approving such an undertaking and including the proposal that such an exhibit be made the nucleus of a permanent public health museum to be housed in some city in the Western Branch area. Your Association committee has offered its

aid to the committee of the Western Branch and the two committees will coöperate in activities looking to the development of a Museum of Hygiene in the West.

Other manifestations of interest have appeared in Philadelphia and Buffalo. In the latter city the Museum of Science has created a " Hall of Man " which was opened in the spring of this year. The exhibit which was brought from the German Hygiene Museum by the Committee on Scientific Exhibits of the American Public Health Association and shown at our Pasadena Meeting has been placed in the Hall of Man for permanent display.

In conclusion, your committee feels that with returning normal economic conditions even further developments of the museum idea may be expected. The committee therefore recommends its continuation.

Current Health Department Practices*

THE Association is constantly receiving requests for information concerning the status and practices of local health departments. These inquiries most commonly relate to personnel and budget. In an effort to meet this demand, in part at least, the Sub-Committee on Current Practices of Health Departments has secured clerical assistance whereby the data coming to the office of the Association through the City and County Health Conservation Contests are recorded on forms displayed in Figures I, II, III and IV.

This information is made available to health officers and others who may request it. The names of the cities and counties together with the years for which data are available appear on the list which follows.

* Report on the work of the Sub-Committee of the Committee on Administrative Practice.

Several very interesting analyses of the data have already been made and published in the *American Journal of Public Health.*

March Journal—A Central Information Service on Current Practices of Health Departments, by Joseph W. Mountin, M.D., presents the purposes of the Sub-Committee and summary tables on total and per capita expenditures in certain cities for health service during the 4 year period, 1930–1933.

May Journal—Specific Expenditures and Personnel of Official Health Agencies in Certain Cities, by Joseph W. Mountin, M.D., presents an analysis of per capita expenditures for the year 1933 by specific functions and an analysis of number of health department personnel employed according to professional classification.

July Journal—Analysis of Public Health Expenditures by Geographic Sub-Divisions, by W. F. Walker, Dr.P.H., presents total and per capita expenditures in certain cities by geographic sub-divisions of the United States. Also brings up to date 1934 (data added) table on total and per capita expenditures by population groups published in March issue of *Journal.*

October Journal—Public Health Expenditures in Selected Cities by Nonofficial Agencies, by James Wallace, M.D., and Louis Feldman, is an analysis of expenditures by nonofficial agencies reported in connection with the City Health Conservation Contests for the 5 year period, 1930–1934.

An effort is now being made to complete the information for the missing years and to expand the list to areas not entered in the Health Conservation Contests. The coöperation of the health officers in this undertaking is essential to its success.

JOSEPH W. MOUNTIN, *Chairman*

Refrigeration of Foods and Its Relation to Present-Day Public Health*

IN accordance with the suggestion of the previous Committee on Foods, your present committee has endeavored to trace recent developments in certain of the food industries with the purpose of evaluating these changes from the standpoint of their relationship to public health. The particular field chosen for our report is that of food refrigeration, a topic hardly capable of complete discussion in the limited time available, but worthy of attention because of its intimate association with the health and well-being of everyone.

Since the invention of the first compression refrigerating machine about 1834, the possibilities of refrigeration have become increasingly apparent, although wide usage of refrigeration facilities has been attained only within the past generation. Today we find refrigeration of paramount importance and a necessity from the standpoint of economics, health, and convenience. The diet of mankind has been materially improved both in variety and quality by refrigeration which enables the year-round consumption of foods from even the most distant countries at prices within reach of the great majority, despite seasonal harvests and long transportation.

Our country is more fortunate in respect to our major food supplies than are some others, such as Great Britain, which draws largely from overseas, but with the increase in uses for refrigeration an industry of great magnitude has developed in the United States to meet augmented needs of this nature. Sir Frank Smith, Secretary of the Department of Scientific and Industrial Research of Great Britain stated last September that the refrigerated space regularly required to transport England's food supplies was equivalent to a floating cold store 20 ft. high, 50 ft. wide and 20 miles long, and that the public cold storage on land amounted in addition to approximately half that content.

In comparison, using statistics presented recently by the American Institute of Refrigeration, the United States in 1931 had refrigerated warehouses which together would approximate a similar chamber 140 miles long, our 119,000 refrigerated freight cars adding 45.5 miles, our ships a further 22 miles, and the domestic mechanical refrigerators sold in the past 5 years another 4.8 miles. Thus we have as a nation a potential refrigerator for foods 50 ft. x 20 ft. over 200 miles in length (or greater than the distance from New York to Baltimore) exclusive of ice boxes in the homes, stores, and restaurants, and the 42 million tons of artificial ice produced during the same year in addition to tremendous quantities of natural ice.

In January, 1935, according to the U. S. Department of Agriculture, there were in cold storage:

Butter	23,587	tons
Cheese	51,098	"
Frozen eggs	32,439	"
Poultry	61,000	"
Meats	479,548	"
Fruits	31,384	"
Fish	34,672	"
Apples	8,890,000	barrels

* Report of the Committee on Foods.

During 1934 we exported 97,715 tons of refrigerated meats and over 544,000 tons of vegetables and fruits.

In 1912 a symposium was held by this Association during which the various aspects of cold storage relating to public health were discussed. At that time refrigeration, or cold storage of foods as it was then termed, was looked on with some suspicion by the general public. In this symposium the late Professor Sedgwick made the following statement:

In short, cold storage is one of the greatest boons mankind has ever known. From the sanitary as well as the economic point of view it is a blessing because it gives us a much greater variety of health-giving food than existed in the older days.

The passage of over 2 decades has amply verified this statement because there has been a great increase in the quantity of foods subjected to refrigeration, the number of products, and the extent to which each is so handled. The necessity for *continuous* refrigeration from the time of harvest or slaughter until consumption is becoming more clearly recognized. The precooling of products before shipment is now commonly practised by many shippers of fruits, vegetables, and other foods, who formerly felt it unnecessary. Careful attention in these respects has doubtless reduced spoilage which is a large factor in our more perishable food supplies.

Today, as was always the case, the refrigeration of foods should be considered as one of the very best means of food preservation, provided it is carried out under proper conditions. Refrigeration never has and never will make good foods out of poor ones, but, fortunately, this fact has become thoroughly understood. It is also evident that the public no longer looks askance at refrigerated foods, because otherwise no such expansion of this type of food handling as has taken place would have been possible.

The "cold storage" label required by law on foods subjected to refrigeration for any length of time has ceased to cast the stigma which in earlier years it sometimes attached to foods preserved in this manner.

Food refrigeration still needs and deserves proper supervision. Only foods of sound quality should be worthy of refrigeration, and such storage should be controlled as to duration, temperature, humidity, and other physical conditions. The various state laws concerning foods and food storage are effective only within their respective borders, while the inspection of all foods entering interstate commerce is vested in the Food and Drug Administration of the U. S. Department of Agriculture, which enforces the federal food and drug acts. The inspection of meats and supervision of packing-house products and cold storage of the same is under the jurisdiction of the Bureau of Animal Industry, and its regulations also apply to all products of this nature which cross state borders.

The quality and edibility of foods, and refrigerated foods as well, is dependent more upon their physiological or biochemical age, if such a term may be used, than on their chronological age. The physiological or biochemical age is dependent on the extent to which the processes of maturation in living materials—such as fruits and vegetables; and the catabolic enzymes contained in dead materials, such as animal products; plus the activity due to the bacteria, molds and yeasts they contain—have progressed, and the changes which have resulted therefrom. In other words, taking eggs as an example, an egg laid only a few days and improperly stored may be of inferior quality to another egg laid the same day but carefully and immediately cooled and maintained under optimum

conditions of refrigerated storage for several months. As time goes on and more is learned about such physiological and biochemical changes, it would seem that the more logical method for the determination of quality and edibility of cold storage products would be the evaluation of such changes, together with the direction of more attention to the preparation of such products for storage, and their actual storage conditions, rather than the emphasizing of storage time, or chronological age, which may sometimes be a fallacy. At present the different state laws concerning cold storage show a considerable divergence in respect to the time limits during which foods may undergo refrigerated storage.

Microbiological studies made on refrigerated foods indicate that not all microörganisms are equally susceptible to the effects of low temperature. Different foods provide media of widely varying chemical composition which influence the reproduction of microörganisms to a marked degree, as do also the temperature and the duration of refrigeration. Certain cold-tolerant types of microörganisms persist in spite of the most rigorous treatment. The usual refrigeration temperatures cut down the rate of reproduction and tend to reduce bacterial counts. At the lower temperatures this effect is more marked, but refrigeration should not be considered a means of sterilization. Refrigeration cannot be expected to be lethal to all food poisoning organisms, or to inactivate bacterial toxins; but it should retard the growth of pathogens and the production of toxins. The proper selection and preparation of foods for refrigeration, sanitary handling of the same, and constant refrigeration until they are used, should minimize hazards.

The sanitation of refrigeration facilities has been improved in recent years. The industry itself has voluntarily made many improvements which have raised standards to a higher level, although due credit must be given to those governmental agencies which have so capably supervised and encouraged such procedures.

Much attention has been paid of late to a study of the best conditions of storage for specific foods, particularly fruits, vegetables, and meats, and it has been found that optimum conditions of temperature and humidity differ to a considerable extent. The storage of foods in the presence of controlled atmospheres containing gases, especially carbon dioxide, has been found desirable in respect to fruits and meats and has recently come into use in English warehouses and ships.

In addition to refrigerated storage and transportation, which may be at temperatures above or slightly below the freezing point, there has been a vast increase in the freezing of foodstuffs. The last decade has seen the birth of a new industry which has already made its impression on the diet of many of our people, namely, that of quick-freezing as distinguished from the older methods.

Another closely allied innovation is the development of quick-frozen methods by which the consumer units of relatively small size can be frozen within the package. This processing of quick-frozen foods, which was first applied to fish, has been extended to many other food products, including practically all meats, shellfish, vegetables, fruits, and even corn on the cob. Certain of the vegetable products are subjected to a short blanching process or heat treatment previous to freezing, in order to inhibit enzyme action with its concomitant changes in color and flavor, and facilitate packing operations. These products even after storage for a number of months at refrigeration temperatures (usually 0° F. or lower) compare very closely in

flavor and taste with the fresh, thus products can be packed at their optimum condition of maturity and preserved in substantially that condition until consumed. This is not the case with many fruits and some vegetables, not frozen, subjected merely to storage at reduced temperatures in transit, as such products are often picked before full maturity.

It must be emphasized that frozen foods, like all other refrigerated foods, require *continuous* low temperatures to minimize the growth of microörganisms and the biochemical activity of enzymes. Unless low temperatures are maintained until the products are about to be used, spoilage will occur and health hazards may result. This is well known in respect to unrefrigerated foods, which may be kept only for limited periods, but it applies equally to those which have been refrigerated or frozen.

Quick-frozen products are now available in many sections of the country where refrigeration facilities at the lower temperatures given are available. The maintenance of such low temperatures for storage warehouses in many rural districts, in retail stores and homes, has been unusual in the past but appears to be on the increase due to this development. In the larger cities such facilities have become quite common.

Numerous workers have been concerned in recent years with the nutritive aspects of foods, particularly from the standpoint of vitamins, and certain of these researches have related to refrigerated foods in storage. More attention in this respect has been paid to fruits and vegetable products and their vitamin C content, because certain of them have attained marked popularity and increased consumption due in part to such content. Such evidence as is at hand indicates that refrigeration of foods containing vitamin C tends to conserve such content in comparison with similar products not refrigerated during storage, although periods of months may diminish the concentration in some foods unless very low temperatures are employed. No evidence that the other known vitamins are deleteriously affected by the use of low temperature has been presented. This applies also to frozen foods.

It is believed that during the past few years of reduced incomes the economies of refrigeration have enabled many families to obtain foods in the fresh form during off-seasons at a cost which might otherwise have been prohibitive, thus allowing better balanced and more complete diets which contribute to the health of the individual.

An example of economy due to refrigeration is the reported distribution to families on welfare of frozen meat produced by the emergency slaughter of food animals in the drought areas by government agencies. These animals, doomed to die of malnutrition otherwise, were conserved or salvaged. It is hoped that such products, helpful as they may be as a source of food, will not be considered by the consumers as representative of the high quality usually found in refrigerated products.

The applications of refrigeration in the food industries have increased markedly in the post-war years. Omitting the dairy industries, which are more properly the field of another committee, it is worthy of mention that refrigeration is now used extensively in bakeries, breweries, candy and chewing gum factories, canneries, food oil hydrogenation plants, cocoa manufacturers, gelatin factories, packing houses, yeast plants, and many others. In some cases the use of low temperatures is for physical reasons, but in large part it is for the conservation of prod-

ucts against spoilage and the possibilities of injury to the health of the consumer. Refrigeration has also been shown to be lethal for various insect pests including the European corn borer. It has also been found effective in killing the larvae of Trichinella spiralis which are the causative agents of trichinosis due to eating pork and its products.

Thus we may visualize refrigeration as one of the protective forces of our community which functions in large part unseen, although those who are observant may note warehouses at our docks and terminals, pre-coolers in the harvest regions, insulated and refrigerated freight cars and fast motor trucks—even tank trucks—display cases in our stores which have vastly improved the retail handling of perishable foods, and the vast army of domestic refrigerators in restaurants, hotels and homes which are of equal importance at the consumers end. More than 5,000,000 mechanical guardians of the home which maintain a constant low temperature have been sold in this country since 1930, giving some evidence of the reliance which our nation places on refrigeration. The use of such facilities will doubtless avoid many unfortunate cases of disease formerly caused by improperly handled foods.

There are evidences that such facilities might well be extended to include the refrigeration of some products not commonly refrigerated at present. Numerous outbreaks of food poisoning have been traced to cream-filled bakery products, some of which have caused deaths. Refrigeration is no substitute for cleanliness or proper materials and procedures in the manufacture of filled bakery products; *but it is recommended as a desirable type of storage for such ingredients as may not be heat treated in manufacture,* in transit, in the food shop, and last, but not least, in the home.

In summation, your committee views refrigeration as a faithful ally and servant to all food consumers, one which has become so intimately connected with our daily life and existence as to be practically indispensable. Like all servants, it requires proper and strict supervision. Fortunately, in this country, such supervision has been both adequate and capable with rare exceptions. The use and advantages of refrigeration bid fair to expand as time goes on, to the benefit of the health, comfort, and pocketbook of our nation.

Your committee recommends the continuation of the work of the Committee on Foods for another year.

Standard Methods for Microbiological Examination of Foods

PROGRESS toward the standardization and simplification of the microbiological analyses of food products has been made along 3 lines, namely, for fermented foods, for meats and meat products, and for shellfish. In accordance with the policy of this committee, bacteriologists experienced in the analysis of these types of foods have been requested to assume the leadership in the development of methods for each product.

Dr. C. S. Pederson, who has long been interested in fermented foods, agreed to promote methods for sauerkraut, pickles and other fermented products. Inasmuch as there is now very little information available on the types of microörganisms present in fermented foods, following the report by Dr. Pederson presented at the American Public Health Association Annual Meeting in Indianapolis in 1933, it seemed advisable to arrange for a series of examinations in various laboratories of both known and unknown samples of fermented foods.

Accordingly, Dr. Pederson prepared an outline of the types of tests he considered important. This outline was submitted to all members of the committee and others who were in a position to make helpful suggestions. The comments of each reviewer have been carefully considered and every suggestion incorporated. With a brief introduction and with some sections expanded to greater detail, this outline will serve as the basis for the examination of test samples soon to be submitted to some 6 or 8 different laboratories.

These preliminary analyses will be made in order to secure information as to the microflora generally found in fermented foods. From such information the methods, culture media, etc., best suited to the needs can be selected. Such general examinations can serve also to acquaint the analysts with fermented foods, as well as with the methods of analysis.

The development of methods for the examination of meats and meat products has received an unexpected and gratifying stimulation. The Bacteriological Sub-committee of the Technical Meat Committee of the National Canners Association has been studying this problem for some time and has joined its forces with the American Public Health Association in order that the greatest progress can be made with the limited personnel available. This is encouraging indeed and it is hoped real progress can be made along this line during the coming year.

In the field of shellfish examinations the committee has been ably represented by Dr. A. C. Hunter, who some time ago was made referee for developing standard methods for the examination of all types of marine products. The Association has been very active in work on oysters, and Dr. Hunter has taken an active part in the conference and developmental work.

At this convention, the results of many thousands of laboratory examina-

* Report of the Committee on Microbiological Methods of Food Examination of the Food and Nutrition Section.

tions on oysters, as well as the results of conferences and questionnaires on methods have been presented. Among these was a discussion by Dr. Hunter of the shellfish report from the control viewpoint.

Many different types of culture media have been used by various bacteriologists for the cultivation of anaerobic bacteria. Beef muscle extracts, beef heart extracts, liver infusions, chicken broths, vegetable broths, etc., all including a small portion of the original plant or animal tissue, have been prepared, used and recommended.

Anaerobic bacteria play an important part in food preservation and food spoilage, so this committee is vitally interested in any and all progress leading toward a more simplified practice in microbiological technic.

An extensive study of the value of different types of culture media for the cultivation of anaerobic bacteria has has been carried out by Dr. L. S. McClung. He was particularly interested in thermophilic anaerobes, but his survey of various media and methods of producing anaerobic conditions briefly summarizes the information to date, so that his selection of a method which is generally satisfactory for the cultivation of anaerobic bacteria is significant. In his study, the sealing of culture tubes with agar proved the most satisfactory. It is simple, rapid, and does not make the tubes difficult to clean, which is a serious problem in large laboratories.

Coöperation in this committee's work has been enthusiastic and it is hoped real progress can be made during the coming year.

Milk and Dairy Products

DURING the past 3 years the Committee on Milk and Dairy Products has endeavored to review the scientific literature on vitamin D milks and to discuss certain aspects of their production which are of direct concern to administrative health officials.

As a result of reported clinical studies on vitamin D milks, a large number of cities have permitted the sale of these products. In some instances, these vitamin D milks are subject to control by means of ordinances or regulations, but in other instances, the sale of these products is not regulated by specific legal requirements.

In previous reports, the committee has attempted to show the status of these milks under existing laws defining milk and milk products. To illustrate the confusion on this subject which still prevails, the U. S. Public Health Service Milk Ordinance, which has been adopted in about 600 communities, merely states that vitamin D milks shall be produced in accordance with standards and regulations prescribed by the health officer, which obviously means that there is and will be an unfortunate lack of uniformity in control of these important products.

In contrast to this may be cited the regulations adopted during the past year by the Board of Health of New York City, which require, among other things, that the source of vitamin D and the number of units per quart shall be stated upon the labels. On the other hand, Dr. Paul B. Brooks, Deputy Health Commissioner of New York State, has expressed the opinion[1] that "no statement as to the number of units per quart shall appear on the cap or label." Since all market milk sold in this state, outside of New York City, is subject to the regulations of the state, this viewpoint, if incorporated in official control standards, would set up conflicting requirements within the same state.

With regard to the labeling of vitamin D milks, there appears to be a divergence of scientific opinion as to the use of comparisons between the potencies of vitamin D, as expressed in units for the several milks, and their equivalents in cod liver oil. This subject deserves careful consideration, with due regard to the results of clinical investigations.

The present mode of commercial advertising of the various vitamin D milks often tends to confuse the consuming public, especially when improper emphasis is given to units or to the question whether a certain milk is produced by "natural" or "artificial" means, when the clinical evidence indicates that all of these milks when properly produced are antirachitic.

Uniformity of administrative control of vitamin D milks of all types is essential. A noteworthy step toward the achievement of uniform standards and requirements for these products has been the establishment of the Vitamin Section of the Drug Division of the Food and Drug Administration of the federal government. In view of the facilities available to this federal agency, it is to be hoped that effective and reasonable standards for vitaminized products may be promulgated. This agency is in charge of Dr. E. M. Nelson, who is the Chairman of the

Committee on Standard Methods of Vitamin D Bio-assay of Milk, of the Food and Nutrition Section of this Association.

In order to standardize more effectively the physical and mechanical aspects of irradiation as applied to milk and to define the product, a conference of technical experts was convened in July in New York City. This meeting was called at the suggestion of the chairman of your committee, in his capacity as a public health official, and held under the auspices of the Wisconsin Alumni Research Foundation. As a result of this significant conference, a permanent committee of physicists, research engineers, and biochemists was appointed to define irradiation, and to formulate specifications for the process. The committee has already prepared a preliminary report. This action is to be commended as a progressive accomplishment looking toward the more effective correlation of a widespread practice of great significance to control officials and to the public health.

The work of this committee should lead to the establishment of reliable irradiation technic and the equipment of machinery with suitable indicating and recording devices which will make possible the official enactment of satisfactory requirements, and will permit of effective supervision by routine inspection. These procedures are analogous to present standards for and inspection of the process of pasteurization.

PASTEURIZATION OF CERTIFIED MILK

The noteworthy application of a scientifically proven safeguard to public health was the approval during the past year of the permissive pasteurization of certified milk, unanimously voted by the American Association of Medical Milk Commissions at their annual meeting in Atlantic City in June, 1935.

Section 58 of the Methods and Standards for Certified Milk has been amended to read as follows:

> Certified milk must be produced strictly in accordance with the Methods and Standards, and when so produced it may be subsequently pasteurized, provided it is labelled on the bottle cap with the words "Certified Milk—Pasteurized" in addition to the other requirements for the capping and sealing of bottles as described in Section 44.

A new section (No. 59) says:

> Pasteurization of Certified Milk must be done on the farm where it is produced and under the existing state and local rules and regulations. Equipment used for the pasteurization of Certified Milk shall not be used for the pasteurization of any other grade of milk.

This important action has been highly commended in editorials in the *American Journal of Public Health* for August, 1935, and in the *Journal of the American Medical Association* for August 24, 1935. Two pertinent quotations from these significant editorials are of special interest.

In discussing the action at Atlantic City, the *American Journal of Public Health* states:

> It was pointed out at that time, and we agree, that the action taken in favor of permissive pasteurization was a landmark in the development of certified milk, an episode which is as significant to dairy science and to public health as was the institution of certified milk itself in 1893. Physicians and consumers who desire a clean and safe raw milk can still obtain it, but an even greater proportion of discriminating physicians and consumers who prefer that the best milk obtainable be pasteurized will at last be satisfied. Health officials will now have added reasons for recommending and advocating increased consumption of these certified milks.

The *Journal of the American Medical Association* states:

> Now that the producers of certified milk and the medical milk commissions have adopted permissive pasteurization there should be benefit to all interested groups. Physicians desiring the highest quality of pasteurized milk for their patients will be able

to prescribe pasteurized-certified milk; producers of certified milk will be able to offer their customers a pasteurized product; public health authorities will be aided in their program of universal pasteurization, and milk consumers will have a wider choice among desirable milk supplies.

Certified Milk—Pasteurized is already on the market in Boston, Cincinnati, Detroit, Miami, and Philadelphia, and plans are under way to distribute it in New York and other large cities after October 15, 1935.

Health officials should endeavor to facilitate the distribution and sale of certified milk—pasteurized, and where necessary should adopt new legislation or amend existing laws to conform to the present methods and standards for certified milk. This has already been done in a number of states and cities. Methods of pasteurization should be those already sanctioned by law or set forth in the U. S. Public Health Service Milk Ordinance.

COMPOSITION OF MILK

The composition of certified milk must conform to rigid standards, based upon the natural characteristics of the dairy animals and influenced by scientific control of the constituents of ration of the cow. In some instances standardization of certified milk was practised, but the system has been discontinued as inadvisable.

Competition for commercial supremacy in the sales of market milks has in recent years often been based on "deeper cream line." Frequently this has led to standardization, by removal of skim milk by the dairyman by several methods, which practices may and do lead to contamination and even adulteration. For these reasons, such methods should not be tolerated. Obviously, if certified milk, which is intended primarily for infant feeding, should not be subject to such manipulation, other grades of milk, which are even more extensively employed as such an important food, should not be altered in composition on dairy farms where chances of serious contamination are likely to prevail.

In a study of standardization of milk on the farm by Button and Perry,[2] the conclusion is reached that practices of siphoning and separating involve unsanitary features; that fore-milking or the removal of skim milk by siphoning or gravity is not economical due to the loss of butter fat; and that the daily variations in herd tests make it difficult for dairymen to standardize their products so that they will contain the desired butter fat content. Unsanitary methods and conditions and financial losses to dairymen are both directly and indirectly of public health concern. In the first instance the product is subjected to bacterial contamination, and in the second case the dairyman is handicapped in his ability to maintain proper methods and equipment.

Perusal of existing laws defining milk reveals that standardization of milk on the dairy farm is generally illegal.

MISINFORMATION ON MILK

Much misinformation on milk and milk products is distributed by various self-appointed consumer organizations. Bulletins and other publications of these groups frequently contain erroneous and prejudiced facts, which are not only unreliable for consumers and unfair to the industry, but reflect upon the skill and integrity of health officials. Such distorted and irresponsible material should be condemned.

CONCLUSION

This report emphasizes the progress which is being made in the official establishment of uniform, reasonable, and intelligent control of various important milk products; point out certain ill-advised practices in milk pro-

duction; and the necessity for the enforcement of existing laws.

Food Fallacies and Nutritional Quackery*

THE popular appeal, through the press and commercial advertisements, of matters relating to food and health has elicited wide popularization, and dissemination of information developed by scientific investigations in the field of nutrition. As a result, we have become as a nation "food conscious." The great popular demand for information about foods and dieting, together with the erroneous idea in many cases that nearly every disease and ailment can be cured by some system or other of dieting, has offered an unusually attractive opportunity for exploitation. During the last few years there has been an increasing amount of publicity, and exploitation of false and harmful statements foisted upon the public by dietary quacks, faddists, and so-called nutrition "experts." Some of them may be honest, but ignorant and misguided enthusiasts and fanatics. Many of them, however, are fakers, so-called "doctors," with little or no recognized professional standing, motivated by personal gain, who have selected this fruitful field for preying on the public.

Notwithstanding the large amount of popular scientific knowledge available in nutrition, the successful preying on the public by faddists and quacks has assumed alarming proportions. Influenced by promises, fanciful appeals to fear, and suggestion, many choose the courses offered by the faddist in preference to the advice of reputable authorities. Unfortunately, a large proportion of the population is unable to discriminate between the claims of the charlatan or ignorant faddist and those of investigators whose scientific contributions and knowledge have gained for them the position of outstanding authorities. Even physicians, nurses, teachers, medical students, and dietitians are numbered among the victims. Aside from mulcting thousands who can ill afford it, the exploitation of these dietary notions is a menace to public health, causing serious injury as a consequence of relying upon these false dietary systems for alleviating their ailments instead of seeking the timely aid of reliable medical assistance.

The most common subjects of the appeal which these quacks make are food combinations and incompatibilities. Based on entirely false representations, vicious systems of dieting which do much injury are given in books and pamphlets sold under high pressure salesmanship.

One of the most common and extensively proclaimed nutritional fallacies is that proteins and starches are incompatible and should be separated into distinct and separate meals. Based largely on this idea a system of dieting has been developed and featured in books and syndicated newspaper columns. A monthly magazine is devoted to this system. It is maintained that because starches require an alkaline medium for their digestion and proteins an acid medium, an antagonistic effect is developed when both are taken

* Report of the Committee on Nutritional Problems.

together which seriously interferes with the digestion of each of these classes of foods. One can look in vain through the writings of authorities in textbooks and journals for any scientific experimental data in support of this idea. The proponents ignore the fact that a large proportion of our staple articles of food contain both starch and protein. Adherence to this system would necessarily eliminate from the diet practically all products made from cereals and grains, such as bread, crackers, macaroni, cakes, pastries, etc. It would also exclude potatoes, beans, peas, and many other important foods. The cereal grains, wheat, rye, barley, oats, and corn, range in their protein content from 9 to 12 per cent or higher, and contain also about 60 per cent starch. Rice contains about 7 per cent protein and upward to 80 per cent of starch. Beans and peas are rich sources of both protein and starch, containing from 20 to 25 per cent protein and 40 to 50 per cent starch. Chestnuts range from 9 to 10 per cent protein and 20 to 30 per cent starch.

This absurd system would ban the time honored combinations which for generations have been recognized as wholesome and healthful, such as meat and potatoes, bread and milk, bread and cheese.

Investigators and authorities in the field of nutrition are practically unanimous in the opinion that there is no incompatibility between starches and proteins in the diet.

> Faddists have hit upon the idea that we should not eat starches and proteins at the same meal because starch digestion is interrupted in the acid stomach, acid being essential to peptic or stomach digestion of proteins. This is a fallacy. There is no significance in this interruption. The cat, dog, and cow have no starch-digesting ferment in their saliva, but they thrive on foods rich in starches. All their starch digestion takes place after the food has left the stomach and reaches the small intestine. Nature did not put these animals at a disadvantage in this respect. *McCollum and Becker.*[1]

> Much of what is said by food faddists relative to combinations of protein and carbohydrate is fallacy without any basis in scientific study. *Fishbein.*[2]

It has been shown that a mixture of carbohydrate and protein foods is discharged from the stomach in shorter time than protein alone, indicating that

> . . . the addition of carbohydrate to the diet accelerates digestion and the discharge of the gastric contents. *Cannon.*[3]

Studies by Rehfuss, Hawk, and others[4] on human gastric digestion in the stomach involving more than 1,000 studies on 200 normal men, in which a great variety of protein and starch combinations was used, failed to produce any evidence whatever of the incompatibility of these 2 classes of foods. In order to meet criticisms of the food faddists, that different results would have been obtained had the studies been made with chronic invalids instead of normal individuals, Rehfuss[5] has more recently extended the investigations to include a cross-section of medical invalids representing almost every variety of chronic illness encountered in a medical work service. Meat was used to represent protein, and potatoes to represent starch. The results of these studies involving hundreds of observations and representing a year's work in medical service, again demonstrated:

> . . . the absolute inaccuracy of the statement that proteins and carbohydrates are incompatible in the stomach. . . . There is no evidence either in the literature or in my investigation to lead me to believe that proteins and carbohydrates are incompatible in the stomach. The danger of such teaching based on a lack of scientific evidence is manifest, and while it may be true that many individuals overeat and are presumably better by a reduction of carbohydrates, the unqualified acceptance of such a teaching can lead to the occurrence of serious malnutrition as well as to a lighting of tuberculosis and old infections.

We are also told to eat but one kind of starch at a time and one kind of protein. This is obviously so devoid of any scientific reason that it merits but a mere passing reference. All starches yield on digestion the same simple sugar, glucose. The end product is the same irrespective of the source of the starch. As to proteins, to eat one kind at a time is just what one should not do. Proteins differ in their nutritive value depending on their amino acid composition. Some proteins are lacking or deficient in certain amino acids which are nutritionally indispensable.

Nutritionally deficient or incomplete proteins should be supplemented with other proteins so that the amino acids lacking in the one will be supplied by the others in order to have an assortment of amino acids adequate to meet the requirements of the body. For example, the endosperm proteins of the cereal grains in general are deficient in lysine and tryptophane, two amino acids indispensable for growth and normal nutrition. The proteins of meat, milk, eggs, and nuts, on the other hand, are excellent sources of these amino acids. The value of the cereal proteins in the diet is enhanced by inclusion of the latter protein foods in the diet. Instead of an incompatibility we have a supplementation.

Acidosis is a term that is frequently and effectively used by the purveyors of food fallacies in the exploitation of their books, literature, and dietetic systems. Nearly all diseases that afflict mankind can be found enumerated as the result of acidosis caused by eating "acid foods." Elaborate menus are offered for "alkali-forming" meals, and systems of dieting which can be had by purchasing their books or enlisting their services and special courses. The claim that acidosis, with all its dire effects, will result from eating bread and meat or certain combination of foods, such as proteins and starches, or fruits and starches, is entirely unsupported by scientific evidence.

Acidosis is usually a condition attending certain diseases, such as diabetes or kidney diseases, involving a faulty metabolism of the body.

There is no evidence that a preponderantly acid diet is injurious.

That the body reaction remains practically unaltered even when a wide range of amount of acid or base is ingested has been pointed out by Henderson.[6]

McCollum and Hoagland[7] found that long continued excess of acid-forming elements in the diet did not lead to any apparent injury.

The Committee on Foods of the American Medical Association in one of its recent decisions states that

> . . . acidosis is a name for a morbid condition of diminution in the reserve supply of fixed alkali in the blood and body fluids. Most people have no conception of the true meaning of the word and are quite likely to confuse it with gastric hyperacidity or "acid stomach," or to conceive of it as "acid blood," a condition which would be incompatible with life. The term "acidosis" is so little understood that its use in any advertising except that restricted to the medical profession is misleading and consequently disapproved.

As stated by Stone,[8] the term acidosis has become a popular fancy.

> . . . The belief that acid-ash foods are responsible for a variety of common symptoms such as gastric hyperacidity, lassitude, biliousness, acid mouths, headaches, nephritis, and high blood pressure carries one far afield. . . . The importance of the acid-ash diet as a factor in the etiology of disease has been overestimated.

Mariott[9] believes that ". . . acidosis is a rare condition and there is no good evidence that the regular taking of large amounts of alkaline-ash foods is of any special benefit." In his experience there is no evidence ". . . that an alkaline-ash dietary

can effect the reduction of established arterial hypertension."

Arthritis is a disease which is commonly emphasized as resulting from improper food combinations and which readily yields to the particular dietetic system which is exploited. We are told to omit "acid fruits and vegetables"; to partake of only one type of food substance at a meal; to alter the acid-base balance of the diet; to use a low protein and carbohydrate diet. Carbohydrate restriction is based on a dietary rationale, the correctness of which has not been satisfactorily demonstrated by scientifically controlled experiments. The commonly so-called acid fruits, such as oranges, tomatoes, and grapefruit, contain weak organic acids which are easily oxidized in the body. These acids are chiefly present as salts of inorganic bases which are left in the blood as alkaline carbonates and really serve as available alkali to the body. The fallacy and inadequacy of these claims have been recently pointed out by Bauer.[10]

> One need make no conscious effort to maintain a basic diet in an arthritic person any more than in a normal one. . . . The prescribing of a low protein diet is a relic from the days when rheumatoid arthritis was confused with gout. There is no justification for the limitation of proteins in the dietary of a patient with rheumatoid arthritis. There are many reasons why it should be liberal.

Another fallacy which finds a prominent place in the armamentarium of the nutritional quack is that acid fruits should not be eaten at the same time with carbohydrate foods, including breads and cereal products, potatoes, squash, and sugars of every kind. These foods, we are reminded, require an alkaline medium for their digestion, and without the alkaline reaction of the saliva they would never be digested at all. This view ignores the well known fact that only a part of the carbohydrate digestion occurs in the mouth and stomach as a result of the action of ptyalin in the saliva, and that there are active amylolytic enzymes in the intestines where carbohydrate digestion proceeds to completion. In fact, starch digestion can proceed favorably in a medium that is practically neutral. The relatively small amounts of the weak organic acids in fruits can have little or no significance in any interruption of starch digestion in the stomach where the hydrochloric acid of the gastric juice is many times stronger than the fruit acids.

Emphasis is laid by "experts" and exploiters of preparations offered for sale on the claim that the use of common table salt is responsible for Bright's disease, cancer, tuberculosis, high blood pressure, and other diseases and ailments.

The surmise that salt has some relation to high blood pressure has influenced to some extent the treatment of this disease. However, the work of O'Hare and Walker[11] lends no support to such a view. No relation was found to hold between blood pressure and the chlorides of the blood and plasma, and no effect on the systolic and diastolic levels was observed during wide variations in the amounts (0.5 gm. to 4 gm. daily) of salt taken in high pressure cases without nephritis. McLester,[12] in a series of controlled observations with patients having hypertension, was unable to note any improvement when a so-called "salt-free" diet was used. He believes, however, that in cases of hypertension complicated with nephritis the salt intake should be restricted "to that contained in the food as it reaches the table." While the avoidance of large quantities of salt in the diet of patients suffering from certain diseases may be advisable, there is no evidence that salt in the quantities generally used in the diet results in the development of such

diseases as mentioned or is attended by any harmful effects.

We are told to avoid the use of dark meats or to limit our meat consumption to fish and fowl. The statement that white meat is less harmful than dark meat has no basis in fact.[12] This belief goes back to the days when gout was confused with other forms of arthritis, and that foods rich in purines yield uric acid with resulting gout, rheumatism, and acidosis. With the exception of the glandular organs, liver, sweetbreads, and kidneys, dark meat contains no more purine bases than does white meat. Fish and fowl contain as much, or more, uric acid-forming bases as beef, veal, lamb, and pork.[12]

It has been proved by numerous investigators [13, 14, 15, 16, 17, 18, 19] that the white of eggs is much less digestible when raw than when cooked. There is even evidence [20, 21, 22, 23] that raw egg white when fed to experimental animals will invariably produce toxic symptoms. Nevertheless, it is still not uncommon to find physicians and nurses prescribing raw eggs for invalids in the belief that they are more digestible and more easily assimilated than when cooked.

Among the dicta of faddists and food charlatans are many so fanciful and absurd that to the person of ordinary intelligence they need no refutation. As illustrations of such fallacies may be mentioned the following: Tomatoes cause cancer; meat makes one sensuous and belligerent; mixtures of incompatible foods explode in the stomach; fish is a good brain food; garlic "purifies" the blood; cream should not be eaten with lobster, strawberries or pickles; fish and celery should not be eaten together; "dead foods" should be avoided in the diet.

Many different systems of dieting and treatments are advocated for weight reduction, some of which are merely scientifically unsound; others are positively harmful and dangerous. Many, eager to conform to the current prevailing fashion of being slender, adopt short-cuts to reduction advertised by food promoters and those interested only in their own personal gains, have done themselves harm, bringing on weakness, nervous irritability, and anemia. Particularly to be deprecated is the use of salts and dangerous drugs. In reduction treatment the first consideration is curtailment of calorie intake, with the object of accomplishing a gradual loss of weight without sacrificing the amount of protein, vitamins, and mineral salts required for normal body needs, nor even of the calories needed as a source of energy for body temperature and for production of work. Many reducing menus are erroneously based on elimination from the diet of individual foods, such as potatoes, rice, cereal products, and butter. In order to assure an adequate balance of food factors essential for health and normal nutrition, it should be remembered that it is not the kind of food that should be restricted, but rather the quantity. As Mendel [24] has aptly stated, "Sanity in diet calls for moderation in eating rather than exclusion of any wholesome food. Even the slenderest persons need some energy for their daily undertakings."

It is only by a process of education that the public can be enabled to discriminate between the fallacies proclaimed by the food faddists and quacks, and the sound principles of nutrition established by reliable investigators. Public health officials are in an excellent position to render a great service in educating the general public along these lines, and in waging a concerted attack on the operations of these enemies of public health.

There is plenty of reliable literature available which can be effectively used in conducting such a campaign of education.

In addition to the references already cited in this report, there are given others [25, 26, 27, 28, 29, 30] which excellently cover the subject.

Standard Methods of Vitamin D Bio-Assay of Milk

IT is obvious that the appointment by the Association of Official Agricultural Chemists of an associate referee, Dr. Walter C. Russell, to study the problem of a standard method for bio-assay of vitamin D in milk constitutes a duplication of effort in our two societies. Accordingly, your committee proposes to collaborate in so far as possible with the associate referee of the other association and to draw its own conclusions from the evidence which has been collected by one of us for joint information. The data already collected by Dr. Russell which will soon be considered by your committee independently pertain to the 5 following topics:

1. Duration of the test period
2. Method of feeding the milk, comparing the results obtained by incorporating the milk in the basal diet, with those obtained by feeding it separately from the basal diet
3. Suitability of basal diets for control animals which receive cod liver oil
4. Methods of preserving milk during the period of test
5. The suitability of a reference oil as a standard for comparison

It is planned to continue further collaborative work on all 5 of these items, and upon such others as appear to your committee to be pertinent. The bio-assay of vitamin D milk should obviously follow the principles of the method laid down in the United States Pharmacopeia, which became official on January 1, 1935.

Pneumoconiosis

THE current use of a variety of classifications for the roentgenological appearances of silicotic lesions is making it difficult to correlate the results of a rapidly increasing number of observers. In South Africa, where silicosis is a product of a single industry, and where the problem is handled almost exclusively by a bureau of the government, the classification that has evolved is entirely adequate for their purposes; but in a highly industrialized country silicosis develops in a great variety of occupations. A diagnosis may be required of a physician in a plant, in a public health office, in a sanatorium, or in the physician's private office. Sometimes he may have had little experience in the interpretation of roentgenograms of the chest, and will be forced to lean heavily on the interpretation of a roentgenologist.

The legal aspects of the problem have placed grave responsibilities on the medical profession and have often been a source of embarrassment. Only the physician who has examined the subject has obtained an occupational history of an adequate exposure to silica dust, and has before him a suitable roentgenogram of the chest, should make the diagnosis of silicosis. The roentgenologist, not in possession of these facts, can merely state whether the shadows which he sees in a film are consistent with this diagnosis.

If objective terms descriptive of the type of pathological changes could be generally adopted, material progress would result. The clinician would not have to accept a diagnosis from the roentgenologist; general students of the disease would be able to correlate the findings of the various observers; and more accurate definition of roentgenograms would be available for medico-legal purposes. Roentgenograms of the chest, which are notoriously difficult to reproduce as illustrations, could be described in word pictures capable of interpretation in the light of the personal knowledge of the observer. An error in diagnosis need not necessarily be passed on to others not in possession of the original film.

With these obstacles in mind, a committee has been at work for the past 2 years preparing a tabulation of the various lesions of silicosis together with terms that attempt to depict the character of the shadows cast on an X-ray film by these lesions. This report is submitted to invite criticism, in the hope that the terms suggested, or others of a similar nature, will be generally adopted.

It should be distinctly understood that the tabulation which follows applies only to silicosis, that form of pneumoconiosis which results from the inhalation of dust with a high silica (SiO_2) content.* Other forms, like asbestosis, are excluded from this consideration because their pathology is essentially different from that of silicosis.

The tabulation contains two columns: On the left are the roentgenological appearances and on the right are the corresponding pathological lesions. There is further subdivision to

* Some of the non-siliceous components of certain industrial dusts seem to modify the pathological reactions, but the character of shadows cast by these modified lesions is not sufficiently defined at the present time to include them in the tabulation. Later, when more information has accumulated, certain other terms may have to be included.

HEALTHY LUNGS AND ADNEXA

Roentgenological appearances	*Histological appearances*
1. *Healthy lungs*—As defined by the N.T.A. Committee report.	1. Essentially the normal tissues of the vascular tree, the mediastinum, the bronchi, and trachea.
2. Irregular exaggeration of the linear markings, with possibly some beading confined to the trunks.	2. Cellular connective tissue proliferation about lymphatic trunks in the walls of vessels and bronchi. Beading may be due to various causes, as blood vessels seen end on, arteriosclerosis, minute areas of fibrosis in lymphoid tissues along the trunks.
3. Increased root shadow.	3. Cellular reaction in the tracheo-bronchial lymph nodes with extensions along afferent lymphatic trunks.

These changes come within normal variations when not accompanied by recognized organic disease.

SIMPLE SILICOSIS

4. *Nodulation*—Discrete shadows not exceeding 6 mm. in diameter, tending to uniformity in size, density, and bilateral distribution, with well defined borders surrounded by apparently normal lung shadows. The outer and lower lung fields characteristically show fewer nodules.	4. Circumscribed nodules of hyaline fibrosis located in the parenchyma of the lung. Occasionally some of these nodules may show microscopic foci of central necrosis.
5. Conglomerate shadows that appear to result from a combination or consolidation of nodulation usually with associated emphysema manifested by— a. Localized increased transparency of the lung with loss of fine detail b. Intensification of the trunk shadows by contrast. c. Depression of the domes with possible tendency toward individualization of the costal components of the diaphragm. d. Lateral view: Increase in the preaortic and retrocardiac space with exaggerated backward bowing of the spine. Widening of the spaces between the ribs may or may not be present.	5. The result of coalescence of discrete nodules; an area in which the nodules are closely packed and most of the intervening lung is replaced by more or less hyaline fibrous tissue. The lung architecture is partially obscured. No demonstrable evidence of infection. Emphysema is a compensatory dilatation of the air spaces with or without thickening of the septa.

describe the appearances of: (1) healthy lungs, (2) the uncomplicated silicotic lung, and (3) lung of silicosis with infection. The changes described under the first division are those compatible with a state of good health; and while they *may* be produced by the inhalation of relatively small amounts of silica dust, they are not sufficiently characteristic or advanced to substantiate a diagnosis of silicosis. Similar or identical appearances may also result from the inhalation of non-siliceous dusts, from certain infections, from cardio-vascular disease, and from certain other rare conditions. The changes involved are for the most part confined to the lymphatics and perilymphatic connective tissues and do not often affect the parenchyma of the lung. Since, by definition, silicosis is a disease characterized by nodular fibrosis in the parenchyma of the lung, these alterations, even when they may have been caused by inhaled silica, do not constitute a basis for a diagnosis

SILICOSIS WITH INFECTION

The characteristic appearances described under simple silicosis are modified by infection as follows:

6. Localized discrete densities and/or string-like shadows accompanying those of simple silicosis described above.	6. Strands of fibrous tissue, often along trunks and septa, with or without areas of calcification; indicative of "healed" infection.
7. *Mottling*—Shadows varying in size with ill-defined borders and lacking uniformity in density and distribution, accompanying simple silicosis.	7. a. Areas of broncho-pneumonia with or without caseation, *i.e.*, acute infection. b. Lobular areas of proliferative reaction with or without caseation, *i.e.*, chronic infection.
8. *Soft nodulation*—The nodular shadows described under simple silicosis, 4, have now assumed fuzzy borders and/or irregularities in distribution. The change may or may not accompany the simple mottling of 7.	8. Perinodular cellular reaction either exudative or proliferative in character.
9. *Massive shadows* of homogeneous density not of pleural origin symmetrically or asymmetrically distributed.	9. Extensive areas of fibrosis probably due to organized pneumonia of tuberculous or non-tuberculous origin superimposed upon a coexisting silicotic process. Outlines of normal structures may be partially destroyed.

of silicosis. The second group covers the discrete and conglomerate nodular fibrotic reactions of simple silicosis. The last group deals with silicosis complicated by infection. In the majority of instances the infecting organism is the tubercle bacillus, but the classification is sufficiently broad to include other types of infection. Certain criteria by which one attempts to differentiate various forms of infection will be discussed.

COMMENT

For the first group of appearances we have adopted the nomenclature of the National Tuberculosis Association Committee and described the lungs as *healthy* rather than as *normal*, as a perfectly normal adult human being is a great rarity. For a description of the roentgenological appearance of the healthy chest the reader should consult a paper by Pancoast, Baetjer, and Dunham in the *American Review of Tuberculosis* for 1927 (vol. 15, pp. 429–471).

As already mentioned under 2, *Irregular exaggeration of the linear markings with possibly some beading,* belongs in the healthy chest group even when found in persons with a history of considerable exposure to silica, for such changes are nonspecific in character and they do not involve the parenchyma of the lung. Silicosis as a clinical disease begins only when the lung proper is affected. Likewise, under 3, *Increased root shadow* may be of nonspecific origin and hence is not diagnostic. In the *early* stages of silicosis the mediastinal shadow may be widened, owing to the enlargement of the tracheo-bronchial lymph nodes from accumulated dust and cellular reaction to it; later, when specific fibrosis develops, the tissues generally contract and the nodes decrease in size. The changes described under 2 and 3 may be caused by many forms of irritation; if they are due to silica they are identifiable only by miscroscopic examination. They do not apparently interfere with respiratory function, and they are not of diagnostic significance.

The second group of changes is

limited to *simple silicosis* uncomplicated by demonstrable signs of infection. This condition is characterized by the presence of small, discrete nodules of fibrous tissue disseminated throughout the functional parts of both lungs. The lesions and the shadows cast by them tend to be spherical, hard, sharply defined, and vary in size from 2 to 6 mm. While the distribution is usually uniform throughout both lungs, the extreme apices and the outer portion of the bases are frequently uninvolved. In less advanced cases the nodules remain discrete and separated by air-containing tissue. Irvine has aptly compared the shadows observed in the roentgenogram of the silicotic lung to those cast by a tree. In the earliest stages, when the reaction to silica is confined to the perilymphatic connective tissues, producing an accentuation of the linear markings, the shadow cast is that of a leafless tree. As small nodules begin to appear in the parenchyma of the lung, the tree begins to bud and the shadow of its branches is less clearly defined. When the tree is in full leaf, the stage of advanced nodulation, the shadow of the branches is completely obscured. Previous classifications have been concerned largely with the degree of nodulation as determined by the size and number of the nodules in the lung. We will not attempt to deal with this problem here, but choose to leave the "stage" of the silicosis to the internist, who has physical findings as well as a roentgenogram at his command.

Number 5 deals with the *conglomerate shadows* of simple silicosis, which appear to develop from a combination or consolidation of discrete nodules. The resultant lesion and the shadow that it casts are often difficult to distinguish from the *massive shadows* of silicosis with infection, 9. It is generally assumed that conglomeration results from accidental overlapping and fusion of discrete nodules when they become very numerous; but since conglomeration is usually a localized affair and does not occur in the same position of the lung of every individual, it is logical to inquire why the nodules happen to fuse in one portion of the lung and not in others. Microscopic examination of the tissues from such areas reveals no evidence of active infection. The nodules seem to be much closer together than in other portions of the lung, they are less uniform in size; and they are usually embedded in a matrix of diffuse fibrous tissue having the same characteristic hyaline appearance as that forming the nodules themselves. It seems probable that conglomeration may have occurred because the portion of the lung in question was previously damaged by a localized inflammatory process occurring before or during the early period of dust exposure. Because the tissue was injured, more dust would tend to accumulate in the area, the nodules would develop irregularly and would frequently be very close together. The silica lodging in preëxisting granulation or scar tissue would exert its characteristic effect, and a diffuse hyalinization would result. This explanation for conglomerate reaction is at present hypothetical; proof will come from long continued serial roentgenographic studies of groups of persons exposed to silica dust and from the chance autopsy that may be obtainable. To differentiate *conglomerate shadows* from the *massive shadows* of infection, 9, reliance must be placed upon the absence of change in size and character of the shadows in serial films taken over an extended period, and upon the clinical findings in the case.

Emphysema is usually associated with far advanced silicosis and it is particularly liable to complicate conglomerate nodulation. It occurs in the

immediate vicinity of the conglomeration as a result of the distortion produced by contracting scar tissue; there is also a generalized "compensatory" emphysema found along the borders of the lung, particularly at the bases. The latter type is also common in far advanced generalized nodulation.

In the last group, *silicosis with infection*, are included all cases with detectable evidence of infection whether active or inactive. In this respect we depart from the South African procedure, which includes here only active infection. The difficulty of determining activity, particularly in the silicotic subject, is our chief reason for this arrangement.

Number 6 covers foci of healed infection. Identification of such changes depends upon the same criteria that are generally employed in otherwise normal individuals. In the silicotic subject the shadows usually occur upon a background of generalized nodulation, although in some cases there may be a distinct tendency toward excessive nodulation in the immediate vicinity of the scars left by the infection. Where the exposure to dust has been limited, the major evidence of nodulation may occur about the foci of healed infection with much less reaction in the remainder of the lung. The string-like shadows of healed fibroid tuberculosis are not difficult to interpret if they occur in the classical location, *i.e.*, in the upper third of the lung. In the lower lung they present a problem whose solution depends largely upon the experience of the roentgenologist.

The term *mottling*, 7, we have reserved to describe the shadows of infectious lesions in contradistinction to *nodulation*, which is restricted to those of the silicotic dust nodule. It is essential that this distinction be appreciated and recorded in the terminology. In tuberculosis, mottling is due to bronchogenic or aspiration foci of disease which exhibit a characteristic clustered arrangement. The lesions may be exudative (acute) or productive (chronic) in type; the difference will be registered on the roentgenogram by a mottling which is fluffy and ill-defined, or hard and sharply defined as the case may be. The distribution of the mottled foci, together with the presence of large foci of older disease interpreted as tuberculosis, and clinical and laboratory findings establish the character of the infection. Mottling due to chronic infection that has developed previous to or simultaneously with the relatively early periods of dust exposure may exhibit little or no effect from the inhaled silica for many years. In non-tuberculous broncho-pneumonias the large chronic foci are absent, and the disseminate mottling may involve different parts of one lung or of both lungs. In many instances the nature of the infection must be established by serial examination over considerable periods of time and by careful correlation with clinical and bacteriological findings.

Soft nodulation, 8, is a term that has been coined to describe a rather uncommon combination of silicosis with infection, usually tuberculous. The ordinary hard, sharply defined nodular shadows of simple silicosis, under these circumstances, appear to have enlarged and lost definition. Their borders are now fuzzy and blend imperceptibly with the surrounding lung structure. Such lesions generally occur in association with localized conglomerate shadows in the apex or other portions of the lung. Histologically the infection appears to have localized in and about preëxisting silicotic nodules so that each is surrounded by a zone of exudative or productive cellular reaction.

Massive shadows of homogenous density, 9, are cast by the areas of combined silicosis and infection, usually

chronic in nature. The two processes appear to have developed simultaneously, and unusual amounts of dust accumulate in the diseased areas. Generalized nodulation usually occurs throughout the remainder of the lungs. Pleural densities can be differentiated in stereoroentgenograms, and by over-exposure it often becomes possible to penetrate the extremely dense intrapulmonary areas and analyze their internal structure. Not infrequently cavities may be visualized that were completely overlooked with the usual technic. When due to tuberculosis, such lesions are often bilaterally symmetrical. If the process extends to the pleural surface, a tuberculous etiology is postulated, while other infections are more often deep-seated.

Histological examination of such lesions shows conglomerations of simple nodules embedded in masses of more or less perfectly organized granulation tissue. Often the fibrous tissue has undergone the same peculiar hyalinization that characterizes the interior of the silicotic nodule. Usually the outlines of the original lung architecture are completely destroyed. Manifestations of infection depend upon the nature of the process—if tuberculous, there will be foci of caseation and possibly small cavities. Calcification is not infrequent. If the process is inactive, the presence of fibrous tubercles which do not exhibit the hyalinization of silicosis may be present. The occurrence of giant cells is helpful. A partially organized nontuberculous pneumonia usually contains foci of acute exudation of variable size. Clinically such unresolved pneumonias frequently exhibit periods of exacerbation followed by regression. They may be due to a great variety of organisms, including the Friedlander group and oral anaerobes. Where all manifestations of activity have disappeared, the lesion is probably best classified as a conglomerate shadow of simple silicosis, 5.

The differentiation between these *massive shadows* of infectious origin and the conglomerate shadows of far advanced silicosis is difficult and not always possible. Repeated reëxamination of the patient for evidence of change in the roentgenographic appearance of the lesion, penetration of the massive areas by over-exposure to analyze its internal structure, the clinical behavior of the patient, and repeated bacteriological examination of the sputum may all be necessary to determine whether an active infection is present.

It is hoped that the suggested terminology will receive a practical test. If others find it usable, the advantage of standard descriptive terms should outweigh the conservatism of those who are already using classifications of their own.

Skin Irritants*

THIS report is in the form of an annotated bibliography of some 782 papers or publications dealing with industrial skin irritants. This is a continuation of similar former reports and covers the period of 1929–1934 inclusive. There is a somewhat detailed discussion of the subject as developed in these papers, with an evaluation of the work as reported, and with an indication of the most interesting and important progress and of new developments in the field.

The bibliography is classified under the following heads:

1. General subjects, including statistical data, general prophylaxis, diagnostic tests and treatment, with special consideration of eczema, and of allergy or sensitization
2. Trade dermatoses
3. Physical irritants
4. Animal and animal product irritants
5. Plant and plant product irritants
6. Microörganisms
7. Inorganic chemical irritants
8. Organic chemical irritants
9. Industrial skin cancers and carcinogenic factors, with a number of papers presenting experimental studies on these lines
10. Medico-legal considerations

The bibliography is supplied with a completely cross-referenced author and subject index.

NOTE: The abstracts on which the report is based are filed (645 of them) in the office of the Committee Chairman in the Hygiene Department of the University of Pennsylvania and are available to interested members.

HENRY FIELD SMYTH, *Chairman*

---

* Abstract of the Report of the Committee. The complete Report will be published by the U. S. Public Health Service.

Standard Practices for Compensation in Occupational Diseases

IN 1929 a preliminary report was submitted to the Industrial Hygiene Section, at Minneapolis, and was distributed in mimeographed form to members of the Section. This material was again revised and submitted to the Committee on Research and Standards, which approved the project for publication. By a grant from the Chemical Foundation, this was done in 1931 and made available to the general public.

This report consisted of a compilation of occupational disease legislation, covering Europe and the Americas. From year to year the committee has reported on the changes in occupational disease legislation, so that the original report of 1931 has been kept up-to-date by these supplementary reports.

In addition to this primary study, the committee collaborated with the Committee on Lead Poisoning in 1932, and the Committee on Pneumoconiosis in 1931, in the preparation of standard practices in the compensation for these two diseases.

The committee also prepared an extensive report on the definition of occupational disease in 1932 for the National Committee on Nomenclature.

While the primary objectives of this committee were to study and establish standard practices, it feels that it has achieved only the first of its two purposes. It was hoped that the compilation of occupational disease legislation would be utilized by legislative and social agencies, employees' insurance companies, as well as labor organizations who were interested in improving or changing existing legislation to conform with modern progress and standards. We have been disappointed. It would seem that all the data accumulated by our committee on existing laws, studies, surveys, bills, etc., over the past few years, have not been utilized by law making bodies. This may be seen in the perfect flood of bills that have been introduced in a number of states, all of which, with the exception of those in North Carolina, have disregarded established principles of occupational disease compensation. New York, for example, has passed a blanket occupational disease law which disregards the experience of many countries, like New Zealand, which has changed from a Blanket Law to a Schedule Law.

The failure of this committee to achieve its objective is not due to the nature of the material and reports, but to its make-up. This committee cannot hope to gain a hearing from legislative bodies unless it has the authority that comes from an enlarged representation. Without this it is futile for the committee to continue and it would be well for it to be dismissed. However, if this section feels that it is desirable to pursue this objective of establishing standard practices, it will be necessary to enlarge its representation to include the various interests involved—the employer, the worker, the government, the university, and other social agencies.

We request therefore that the committee be directed to make a preliminary report at the next meeting with a view to determining the feasibility of creating as a projecting aim of this committee and section a central agency representative of all groups in-

terested in the improvement of standard practices in the compensation for occupational disease. This central agency would concern itself with the promotion of education, legislation, research, and the creation of a panel of qualified medical and non-medical experts in industrial hygiene for medico-legal purposes.

Ventilation and Atmospheric Pollution

Part I

Ventilation and Atmospheric Pollution

THE following was approved by the committee and adopted by the Section on Industrial Hygiene at the Milwaukee Meeting as an outline of working standards for atmospheric and space environments for the maintenance of comfort, health, and efficiency, assuming altitudes not exceeding 10,000 feet above sea level *:

1. Cool rather than hot †
2. Dry rather than damp †
3. Still ‡ or moving depending upon physical activity †
4. Some diversity in temperature—time and space—rather than uniformity and monotony †
5. Foot level as warm as head level
6. Radiant source as an item in heating, preferred
7. Graded differences between air-conditioned quarters and outer air, depending upon the length of stay in-doors, *i.e.*, less difference for brief stays
8. Odor-comfort
9. Minimum area for adult person of 25 sq. ft. and cubitage of 200 cu. ft.
10. Reduction of obnoxious dusts, bacteria, fumes, vapors and gases to their sub-danger thresholds
11. Satisfactory primary sense impression upon entering the room or space
12. Maintenance of comfortable conditions during occupancy (room comfort impression)
13. Sufficient replacement of "foul air" with "fresh air" to meet odor-comfort rerequirements
14. Ionization and actinic ray effects on air itself to be disregarded for the present
15. Intelligent supervision

The items of compressed air, ultraviolet rays, X-rays, and radium exposures are not considered here.

* Agreements as to the majority of the exact specifications, of interest to engineers, were summarized in the previous report of this Committee (*Year Book*, A.P.H.A., 1934–1935, pp. 108–112).

† Adapted from the British Health of Munition Workers' Committee, *Memorandum No. 9*, 1916.

‡ "Still" implies air motion under 25 ft. per minute.

Part II

Standard Methods for the Examination of the Air

THE last report to the Association on Standard Methods for the Examination of the Air, known as the "Fourth Supplementary," was made at the New Orleans Meeting, October 27, 1919, by a committee consisting of C.-E. A. Winslow, *Chairman*, T. R. Crowder, W. P. Mason, E. B. Phelps, and C. G. Whipple.

At the Pasadena Meeting, in 1934, the Association Committee on Research and Standards referred to the Section on Industrial Hygiene the matter of bringing this subject up to date. Further instructions were that the Laboratory Section and the Public Health Engineering Section also name representatives for the purpose. Accordingly, the Section on Industrial Hygiene referred the matter to its Standing Committee on Ventilation and Atmospheric Pollution, the personnel of which is named in Part I. Through the good offices of the secretaries of the other named Sections, the two following gentlemen accepted invitations which completed the present committee: G. L. A. Ruehle, of the Food and Drug Administration, U. S. Department of Agriculture, to represent the Laboratory Section; and Harry B. Meller, Head, Air Pollution Investigation, Mellon Institute for Industrial Research, to represent the Public Health Engineering Section. For convenience, this newly constituted committee was named the "Special Committee on Standard Methods for the Examination of the Air."

The plan of procedure adopted was to divide the subject into 4 parts: Physical, Chemical, Dust, and Bacteriological. Specialists in these various fields were then sought and requested to draft the respective reports wanted.

The committee is especially indebted to the following gentlemen for reports on 3 of the 4 divisions (as submitted below):

C. P. Yaglou, Department of Industrial Hygiene, Harvard School of Public Health, Boston, Mass.

Warren A. Cook, Chief Industrial Hygienist, Connecticut State Department of Health, Hartford, Conn.

J. J. Bloomfield, Office of Industrial Hygiene and Sanitation, U. S. Public Health Service, Washington, D. C.

Their reports, it is believed, take up, by inclusion and references, the most immediately needed features and with a minimum of overlapping.

The fourth division—Bacteriological—has still to be drafted, and the committee hopes to be able to secure the services of a well known investigator to assume the task and present his report in time for the next Annual Meeting of the Association, to be held in New Orleans, 1936.

At the Milwaukee meeting (October, 1935), it was further decided to include the original drafters in the personnel of the committee and ask each to head-up a sub-committee to keep in touch with the developments in his special field and to report at intervals, as seems desirable. Comments and suggestions are invited, and may be taken up with any member of the committee as befits the subject matter.

Physical Procedures in Air Analysis

Instruments and Methods for Recording Thermal Factors Affecting Human Comfort

C. P. YAGLOU

1. Temperature: Mercury or alcohol thermometers capable of recording temperature within 0.5° F.
2. Humidity: Sling psychrometer
3. Air movement: Kata thermometer[1] or heated thermometer[2]
4. Radiation: Thermo-integrator[3, 4] or heated globe thermometer[5]
5. Combined effects of 1, 3, and 4, under conditions of minimal perspiration: thermo-integrator or heated dry globe thermometer
6. Combined effects of 1, 2, and 3 under conditions of maximal perspiration: effective temperature index[6] or heated wet-globe thermometer

Comfort in so far as heat or cold is concerned is associated with a normal heat balance between heat production and heat loss, at normal body temperature, and without sweating. Four of the basic factors affecting human comfort are air temperature, radiation, air movement, and humidity. No one of these is independent of the others, but their effects are quite different under conditions of minimal or maximal perspiration.

In men at rest under comfortable air conditions, the total metabolism remains constant, but the proportion of heat loss by radiation and convection may vary depending upon the external conditions. In still air, radiation accounts for about 45 per cent of the total heat loss, convection for 30 per cent, and evaporation for 25 per cent. About 11 per cent of the total heat loss takes place by evaporation from the lungs and 14 per cent from the skin. The former depends on the relative humidity, varying from about 12 per cent at 20 per cent R.H. to 9 per cent at 100 per cent R.H. Evaporation through the skin is limited to the output of water. Insensible perspiration is now believed to be chiefly a filtration of water from the capillaries, so that alterations in humidity may cause no alterations in water loss from the skin, except in so far as capillary pressure is affected by circulatory adjustments (Bazett, Phelps, Adolph).

Sweat gland activity is an emergency process which comes into play in warm environments, omitting psychic disturbances and the like. The output of sweat is controlled by temperature. With unlimited perspiration, the amount evaporated depends upon vapor pressure and air movement.

From this it is clear that in ordinary conditions the rate of heat loss from the body and the degree of comfort experienced depend largely upon the combined effects of radiation and convection.

The ordinary thermometer fails to give an indication of these effects because it is not sufficiently affected by radiation and little if any by air movement. A room may feel too cool at 75° or too warm at 60°, depending upon these radiation convection effects.

The effective temperature index also fails in this respect because it does not allow for radiation effects; it overestimates the influence of humidity at ordinary room temperatures; and it

underestimates the cooling effect of low air velocities.

The dry Kata thermometer is oversensitive to air movement while the wet Kata is oversensitive to both wet-bulb temperature and air movement.

Various instruments have been devised to register these radiation convection effects for the purpose of ascertaining the relative comfort of various environments and for studying the effectiveness of different methods of heating and ventilation. The principal ones are (a) Dufton's eupatheoscope,[7] (b) Vernon's globe thermometer,[8] (c) Winslow and Greenburg's thermo-integrator,[3, 4] and (d) Yaglou's heated globe.[5]

The eupatheoscope is an elaborate laboratory instrument designed especially for conditions prevailing in England. Modification is necessary for use in hot weather. It is not entirely suitable for routine measurements in the field, and the cost is quite high.

Vernon's globe thermometer is the simplest of all. It consists of a 6″ blackened copper sphere with an ordinary thermometer in the center. It is best suited to rooms heated by radiant methods. Its readings are sometimes misleading in rooms heated by convection methods. For instance, if the surrounding walls and glass are below air temperature, the globe will indicate in still air a temperature below that of the air, but if the air is set in motion the globe temperature will increase, approaching the temperature of the air as the velocity increases. Thus the cooler of the two conditions (that with high air movement) would give the higher reading on Vernon's globe. When the air and surrounding surfaces are at the same temperature, Vernon's globe records air temperature no matter what the velocity may be.

The thermo-integrator is a decided improvement over the eupatheostat with respect to both principle and operation. It consists of a blackened hollow copper cylinder 24″ long and 8″ in diameter, with hemispherical ends, containing an electric heating element of 21.5 watts (a storage battery furnishes the current). This is equivalent to a heat dissipation by the instrument of 17.5 B.t.u. per square foot per hour. Eight iron-constantan thermo-couples are distributed over the surface of the instrument, and the mean surface temperature is recorded automatically. This gives a valuable index of the radiation-convection condition of the environment to which the instrument is exposed.

The heated globe thermometer consists of 2 or 3 hollow spheres, one inside another, with air spaces in between to simulate the air spaces in between the clothing of a man. The outer sphere is a blackened standard 6″ tank float. The innermost sphere contains a heating element of variable resistance suitable for connection to the ordinary lighting circuit. The heat input is kept constant for any particular scale, but the amount can be varied by adjusting the resistance from a minimum of 15.3 B.t.u. per sq. ft. per hr. for men at rest, to a maximum of 75 B.t.u. or more for men at work, thus giving a variety of scales for various rates of work. During the heating season the electrical input is at the rate of 15.3 B.t.u./sq. ft./hr. for men at rest, and the surface of the outer sphere is kept dry. In summer the heat input is increased to 20.5 B.t.u./sq. ft./hr. and the lower half of the globe is moistened by fitting on a knitted woolen cap with a tassel which dips into a small bottle of water. When physical work is done at a rate which induces general sweating, the whole surface of the globe must be covered with a wet cloth and the electrical input increased to correspond with the total metabolism. An ordinary glass thermometer inside the outer

air space of the instrument registers a temperature comparable to that existing in the human body between the two outer layers of clothing. The readings of such a globe thermometer seem to be closely related to sensations of warmth and comfort induced by various air conditions.

A single 6″ heated globe with a thermometer close to the inner surface of the wall is as good as a triple globe for physical records of the intensity of radiation and convection. A cadmium plated cylindrical heater ⅜″ in diameter by 1½″ long, slipped over the bulb of an ordinary glass thermometer, is used as an anemometer by means of which air movement may be determined within ±¼ ft. per min.

How valuable the thermo-integrator or heated globe may be as a measure of atmospheric comfort remains to be seen. All four instruments apply during the heating season when the usual changes of humidity exert but a minor rôle upon comfort and sensations of warmth. Under conditions of sensible perspiration it would be desirable to retain the effective temperature index, at least for the time being, for it is difficult to reproduce the surface wetness of clothing and exposed skin by the addition of a moist covering to any of the four devices described.

DESIRABLE AIR CONDITIONS

The test for adequate air conditions should be the comfort of the individual, his psychological and physiological reactions to the conditions, and, last but not least, his inclination for work. No single comfort standard can be fixed to meet every purpose. The requirements differ according to the state of health, sex, age, clothing, activity, and degree of acquired adaptation.

For persons at rest or in sedentary occupations, the air conditions shown by the comfort zones of the A.S.H.V.E.[9] will generally prove satisfactory, provided a correction is made for radiation-convection effects, whenever necessary, by the use of the thermo-integrator or the heated globe thermometer. Such a correction may be made by using the radiation-convection temperature shown by the heated globe thermometer instead of the dry bulb temperature in computing the effective temperature.

For men at work definite standards for physical air factors are almost impossible to establish owing to the chang-

TABLE I

METABOLIC RATES OF MEN IN VARIOUS TRADES AND PROBABLE EFFECTIVE TEMPERATURE REQUIRED FOR COMFORT

	B.t.u. per Hour	*Authority*	*Probable Desirable Effective Temperature for Comfort* [10, 11, 12]
Seated, at rest	384	A.S.H.V.E.	*66* *
Tailor	482	Becker and Hamalainen	65
Bookbinder	626	Becker and Hamalainen	64
Shoemaker	661	Becker and Hamalainen	63
Carpenter	762–963	Becker and Hamalainen	62–58
Metal worker	862	Becker and Hamalainen	59
Painter (of furniture)	876	Becker and Hamalainen	59
Man sawing wood	1,797	Becker and Hamalainen	42
Maximum exertion	3,333 to 4,762	Henderson and Haggard	?

* Value holds for comfort during the heating season. In summer the probable comfortable E.T. varies from 68 to 75 E.T. depending upon prevailing outdoor temperature and conditions of exposure.

ing character of the requirements, particularly with respect to the type and rate of work, type of occupancy, duration of exposure, clothing, adaptation, etc. Each industrial process presents its own factors. The manufacturer should study and regulate conditions so as to bring about maximum comfort and work output.

A suggested schedule of desirable air conditions in various trades is given in Table I on the basis of total metabolism during work. The values are rough estimates indicative only of the extent of the variation in the requirements of industrial workers.

Chemical Procedures in Air Analysis

Methods for Determination of Poisonous Atmospheric Contaminants

WARREN A. COOK

THERE is at this time no central source of information readily available on methods of determination of air-borne poisons. The only treatise on this subject appears to be a Russian publication of 188 pages, *Methods for the Determination of Obnoxious Gases and Vapors in the Air,* by A. S. Zhitkova, which appeared in 1934. An English translation has been made of this but it has not yet been made generally available. Although its bibliography refers, with a few exceptions, to Russian authors, and the author had apparently little access to recent American literature, this publication has a definite value.

Information on the determination of obnoxious materials found in the atmosphere is scattered throughout a variety of books, journals, and reports. Many of the published methods do not include collection of the material from the air nor discussion of the application of the methods to specific conditions.

A comprehensive work on the subject of determination of poisonous atmospheric contaminants may well be undertaken, it would seem, by the standing Committee on Ventilation and Atmospheric Pollution whose reports should present the consensus of opinion of those actively engaged in the field. Approach to this task by a sub-committee appointed for the purpose seems therefore especially desirable. The subject is dynamic, papers being constantly published on new or improved methods. At this time when great interest is being evinced in this field, it also seems desirable to correlate the available methods to the end that more reliable work can be done, that results of various interested investigators may be comparable and that re-duplication of effort in the development of new methods may be avoided.

Such a sub-committee's work may well be directed along the following lines:

1. The preparation of a list of the more common poisonous atmospheric contaminants together with satisfactory methods for the determination of them in the air, and original references to these methods
2. The preparation of a list of the toxic thresholds of these materials under varying conditions of time and concentration
3. The preparation of a list of those injurious materials for the determination of which new or improved methods should be developed
4. The preparation of an annual annotated bibliography of the literature on the subject
5. The collection of information from those actually using the various methods to ascertain their reported reliability for various applications
6. The affording of a means of exchange of information and experience among those working in the field
7. The stimulation of further research in the whole field on a broader and firmer basis

The present report is limited to a brief discussion of the first item in the above outline, viz., methods for the determination of the more common inorganic toxic materials to which workers are exposed.

METHODS AVAILABLE FOR THE DETERMINATION OF POISONOUS ATMOSPHERIC CONTAMINANTS

The types of methods which are of greatest utility are those which permit obtaining the result at the time and place of the determination without recourse to the laboratory. Methods of this type are principally those based on physical and physico-chemical phenomena. Those which have the widest use are (1) the portable interferometer, (2) combustion apparatus, usually depending upon catalytic combustion, (3) adsorption on solid materials such as activated charcoal and silica gel, (4) apparatus dependent upon the thermal conductivity principal, (5) methods based on refractive index, (6) micro-chemical methods, (7) spectroscopic methods, and (8) electroscopic methods.

Most of the above methods are applied to the determination of gases and vapors in air. Portable equipment based on the principles of interference of light, catalytic combustion, and thermal conductivity are now manufactured and may be applied to a wide variety of vapors and gases. While further developmental work should be conducted on certain of the applications of these instruments, these and other physico-chemical appliances possess the advantages of being less laborious than chemical methods, of frequently permitting immediately available results, and of enabling the plant engineer himself, in many instances, to obtain the desired information. The major disadvantage of most of the above methods is that they are not selective for any one of a mixture of gases or vapors but show the sum of all present. However, the information concerning the total concentration of a gas or vapor is often sufficient to serve as a basis for judgment of the presence and extent of the health hazard presented. Where more specific information is required, as to the concentrations of one of several gases or vapors, chemical methods must usually be employed. Chemical methods are also more generally applicable to solid materials in the air.

CHEMICAL METHODS

The determination of injurious materials in air by means of chemical methods usually involves three steps: (1) A satisfactory method of collection of the material, (2) the separation of the material from interfering substances, and (3) an appropriate procedure for determining extremely minute quantities.

COLLECTION OF THE SAMPLE

Since the amount of the injurious material in the air is usually very small, the method of collection of the sample usually involves passing a large volume of air through an apparatus which retains the material to be analyzed. Since the impinger apparatus (described by Bloomfield in another section of this report) samples air at the high rate of 1 cu. ft. per min., this device is of value where it is shown that it collects the injurious materials with the necessary efficiency. Even where gas sampling bottles of the most efficient types are used, it is desirable to conduct laboratory tests to determine their efficiency at a given sampling rate before using them in the field. This caution may also be suggested in the use of all methods for determining atmospheric constituents.

METHODS OF DETERMINATION

A list of the more common inorganic atmospheric contaminants is appended together with references to methods for their determination in air. Many of these methods have been actually used for making field determinations and have been found to be satisfactory by the writer; others of the methods are

suggested in authoritative literature and are believed to be reliable. It is urged that the use of these methods be subjected to laboratory tests for a given situation before employing them. In due time this committee aspires to give the most satisfactory methods a formal approval.

Material	*Method of Collection*	*Method of Determination*
Oxygen	Take sample of air in gas collecting pipette.	Absorb oxygen in Fieser's solution (alkaline hyposulphite with anthra-quinone-betasulphonic acid). Reference: *J. Am. Chem. Soc.*, 46:2639, 1924.
Ozone	Pass air through alkaline potassium iodide solution in gas wash bottles.	Acidify with sulphuric acid and titrate the liberated iodine with 0.01 normal thiosulphate solution. This method specific only in the absence of chlorine. Reference: Flury, F., and Zernik, F. *Schädliche Gase, Dampfe, Nebel, Rauch- und Staubarten.* Julius Springer: Berlin, 1931, p. 116.
Chlorine	Pass air through o-tolidine reagent in absorption tube described by Porter.	Transfer sample to Nessler tube and compare color with standards after standing for at least 2 minutes. Reference: Porter. *J. Indust. & Eng. Chem.*, 18:730, 1926.
Bromine	Pass air through potassium hydroxide solution in bubbler.	Determine the bromide as silver bromide. Reference: Flury and Zernik. *Schädliche Gase*, 1931, p. 123.
Iodine	Pass air through freshly prepared 10% potassium iodide solution in bubbler.	Titrate with standard thiosulphate solution. Reference: Flury and Zernik. *Schädliche Gase*, 1931, p. 124.
Hydrochloric Acid	Pass air through glycerol-potassium carbonate-water solution of the ratio 1:1:1.	The chloride ion is determined by the Volhard method. Reference: Heller, A. Determination of Hydrochloric Acid in the Air. *Gesundheits-Ingenieur*, 55:261, 1932. *Chem. Abst.*, 27:155 (Jan. 10), 1933.
Hydrofluoric Acid	Pass air through gas wash bottles containing potassium hydroxide solution.	Distil fluorides as hydrofluosilicic acid. Determine fluorides in distillate by titration with thorium nitrate solution using sodium alizarine sulphonate as the indicator. Reference: Willard and Winter. *Indust. Eng. Chem.*, Anal. Ed., 5:7, 1933; Boruff and Abbott, *Ibid.*, 5:236, 1933.
Sulphur Dioxide	Pass air through gas wash bottles containing measured volume of standard iodine solution in potassium iodide to which starch solution has been added. Stop sampling before purple color is entirely removed.	Titrate remaining iodine with standard thiosulphate solution. Reference: Adaptation from Fieldner *et al. J. Indust. & Eng. Chem.*, 11:519, 1919.

Material	*Method of Collection*	*Method of Determination*
Sulphur Dioxide (Cont.)		A detailed account of the iodimetric method given in following reference: Griffin and Skinner: Small Amounts of Sulfur Dioxide in the Atmosphere I. Improved Method for Determination of Sulfur Dioxide When Present in Low Concentration in Air. *Indust. Eng. Chem.*, 24:862, 1932.
	Aspirate the air through an absorber containing hydrogen peroxide and sulphuric acid in an automatic apparatus.	Analysis of samples which are automatically transferred to sample bottles by means of the iodimetric method. Reference: Thomas and Cross. Automatic Apparatus for the Determination of Small Concentrations of Sulfur Dioxide in Air. *Indust. Eng. Chem.*, 20:645, 1928. Thomas and Abersold. Part II of above. *Ibid.*, Anal. Ed., 1:14, 1929. Thomas. Part III of above. *Ibid.*, 4:253, 1932.
Hydrogen Sulphide	Aspirate air through a glass tube containing sensitized granules of activated alumina coated with silver cyanide or lead acetate.	The concentration is indicated by the length of travel of the color change on the granules with a given volume of air sampled or by the volume of air required to produce a standard length of travel. Reference: Littlefield, Yant, Berger. A Detector for Quantitative Determinations of Low Concentrations of Hydrogen Sulfide. U. S. Bureau of Mines, *Report of Investigations No. 3276*, June, 1935.
	Collect sample as given under iodimetric method for sulphur dioxide.	Determine hydrogen sulphide according to method given by Griffin and Skinner for sulphur dioxide.
Sulphuric Acid	Pass air through gas sampling bottle containing sodium hydroxide solution.	Acidify sample with hydrochloric acid and precipitate sulphates with barium chloride.
Sulphur Chloride	Conduct air slowly through a gas washing bottle containing a nitric acid solution of silver nitrate.	Dissolve the precipitated silver chloride in ammonia and again precipitate with nitric acid. Reference: Flury and Zernik. *Schädliche Gase*, 1931, p. 147.
Ammonia	Pass air through sulphuric acid solution in gas wash bottle.	Determine ammonia by A.P.H.A. Standard Method. Reference: A.P.H.A. *Standard Methods for the Examination of Water and Sewage.* 7th ed., 1933.
Nitrous Oxide	Pass air through sodium hydroxide solution in gas washing bottle.	Determine as nitrite in accordance with A.P.H.A. Standard Method. Reference: *Ibid.*
Nitrogen Oxides (Mixture of various oxides of nitrogen, principally NO_2 and N_2O_4)	Pass air through sodium hydroxide solution in gas wash bottle.	Oxidize with hydrogen peroxide and determine nitrates by A.P.H.A. Standard Method. Reference: *Ibid.*
Nitric Acid	Pass air through sodium hydroxide solution in gas wash bottle.	Method of determination similar to above.

Material	*Method of Collection*	*Method of Determination*
Phosphine	Pass air through gas washing bottle containing bromine water or through solution of sodium hypochlorite or bromite.	Expel the bromine. Determine as phosphoric acid. Reference: Flury and Zernik. *Schädliche Gase*, 1931, p. 171.
Phosphorus Trichloride Phosphorus Pentachloride Phosphorus Oxychloride	Pass air through 20% sodium hydroxide solution in gas wash bottle.	Determination of the dissociated chlorine (inexact on account of hydrolysis in the air). Reference: Flury and Zernik. *Schädliche Gase*, 1931, p. 172.
Arsine	Pass the air through silver nitrate solution in gas washing bottle.	Titrate the resulting arsenious acids. Reference: *Ibid.*, p. 179.
	Other methods of analysis are critically discussed by Joachimoglu, *Arch. f. Exper. Pathol. u. Pharmakol.*, 85:32, 1919.	
Carbon Monoxide	The method of choice for low concentrations is that depending upon the combustion method in which Hopcalite is used as the catalyst. The concentration of carbon monoxide is read directly from the dial of a milliammeter calibrated to read in parts per million of carbon monoxide. For higher concentrations the "Hoolamite" detector depending upon the color change produced by liberation of iodine from iodine pentoxide is a convenient method.	
	Collection of sample of air in a gas pipette.	The sample of air is passed through a tube containing iodine pentoxide at 300° C. and the liberated iodine is passed into potassium iodide solution. The iodine is determined by titration with standard thiosulphate solution. Reference: The many methods and references on carbon monoxide determination can be completely handled only by a more extensive treatise.
Carbon Dioxide	Pass air into gas washing bottle containing dilute barium hydroxide solution.	Titrate with dilute hydrochloric acid or oxalic acid using phenolphthalein as an indicator. References: Fieldner *et al.* *Indust. Eng. Chem.*, 11:519, 1919.
Phosgene	Air is passed through gas washing bottles containing 50 c.c. alcoholic sodium hydroxide, prepared by dissolving 40 g. sodium hydroxide in 125 ml. of distilled water and adding the solution to 875 ml. of 95% ethyl alcohol.	Neutralize with nitric acid (approximately normal), using phenolphthalein as an indicator, and the chloride ion is determined by titration with 0.1286 N silver nitrate using sodium chromate as an indicator. 1 ml. of 0.1286 N silver nitrate equals 1,000 p.p.m. phosgene (by volume at 25° C. and 760 mm.) for a 1 minute sample. Reference: *Ibid.*, p. 523.
Cadmium or Cadmium Compounds	Impinger device using water as the liquid.	Precipitate the cadmium as the sulphate and determine gravimetrically. Reference: Treadwell-Hall. *Quantitative Analysis.* Precipitate with hydrogen sulphide, dissolve, remove acid by evaporation, treat with KCN solution and some H_2S water. The color of the precipitate is then compared with that of similarly treated standard solutions under ultra-violet light.

Dust Procedures in Air Analysis

The Sampling and Analysis of Industrial Dusts

J. J. BLOOMFIELD

THE subject of the health of workers in dusty trades has been receiving considerable attention from students of industrial hygiene and others interested in the various phases of this problem. When one realizes that the workmen employed in the dusty trades comprise one of the largest groups exposed to any one industrial hazard, it is quite apparent that the importance of this problem has not been overestimated. Furthermore, it is now well established that exposure to certain kinds of dusts, such as those containing considerable amounts of quartz, has increased the morbidity and mortality rate from respiratory disease; while metallic dusts, such as lead and its compounds, have been associated with general systemic poisoning. Thus, the harmful properties are the composition of the dust, the quantity suspended in the industrial atmosphere, and its particle size.

Investigations of the industrial dust question serve a threefold purpose. First, they enable one to evaluate the extent of the hazard; this is accomplished by obtaining occupational dust exposures, which disclose the dust creating tasks. Second, if clinical studies are also made, dust counts may indicate the permissible amount of dust which may be breathed with impunity. Third, dust determinations are used in an attempt to control the hazard; this is effected by testing the efficiency of devices which have been developed for this purpose.

The quantitative aspects of the dust problem demand standardized procedure in the sampling and analysis of dusts. The American Public Health Association, through its Committee on Standard Methods for the Examination of the Air, made its last report October 27, 1919. This was published in May, 1920.[1] Here it recommended the continuation of the Palmer Water Spray Apparatus as the standard method of dust determination and suggested that if the konimeter[2] or Bill electrostatic collector,[3] developed at that time, proved to be superior, then one or the other of these devices should be adopted.

In 1922, the instruments in common use in conducting dust studies were the Palmer, konimeter, and sugar tube, and, in addition, the U. S. Bureau of Chemistry,[4] in its dust explosion work, employed an apparatus which consisted essentially of an adapter for holding a Whatman filter paper thimble through which air was drawn by a suction pump. By the difference in weight of the paper thimble before and after dust sampling, the weight of the dust was easily determined. Finally, mention should be made of the Anderson and Armspach[5] dust determinator which in 1922 was in use by the American Society of Heating and Ventilating Engineers. This instrument measured the increase of pressure incident to forcing air through a piece of filter paper; this rate of increase of pressure was then taken as a measure of the air dustiness.

However, in the year 1922, it became apparent that the various methods did not yield results which could be

regarded as absolute or even comparable. Consequently, a conference of interested persons was held at the U. S. Bureau of Mines Experiment Station, Pittsburgh, Pa., in 1922, when it was decided to conduct a laboratory study of dust sampling instruments.

Suspensions of dust (5 different powdered substances) were set up in an air-tight chamber at the Experiment Station that year, and simultaneous samplings were carried out with the sugar tube, the Palmer apparatus, the konimeter, the filter paper thimble, and the dust determinator.

During the course of the study, a new instrument, the Greenburg-Smith impinger, for the sampling of dust, was devised (see *Pub. Health Bull. No. 144*). In this instrument, the air to be sampled is drawn through a glass tube and impinged at a high velocity on a glass plate which is kept beneath the surface of the water or other suitable fluid in the collecting flask. The dust is momentarily arrested, wetted by the collecting fluid, and in this manner trapped. After a sufficient volume of air has been sampled, a portion of the collecting fluid is removed to a suitable counting chamber, or cell, for microscopic count, to ascertain the number of particles. The remaining portion of the sample may be subjected to any desired analysis.

In the comparative study, the dust catching efficiency of the impinger was found to be high. Consequently, its physical principles and characteristics were the object of a special study, and finally a satisfactory and practical form of dust sampling instrument, based on this principle, was evolved.*

The apparatus (essentially in its present form), as described in *Public Health Bulletin No. 144,* possessed an efficiency of 94 to 97.5 per cent when sampling a finely divided silica dust suspension at the rate of 1 cu. ft. per minute. The tests used in estimating this efficiency were conducted by an optical method in which a portion of the dusty air delivered to the collecting device was diluted with measured amounts of dust-free air until a "match" was obtained on comparison with the stream of air emerging from the dust collecting device. The comparison, or matching, consisted in producing equal Tyndall effects (equal amounts of reflected light) by the two dust streams when they are simultaneously observed in a beam of light.

So far as the quantitative results of the dust sampling instruments are concerned, the conclusion of the comparative study was as follows:

> Considering the dust caught by the Palmer as unity, the instruments take the following order: On basis of numbers of particles determined—impinger, 5.0; sugar tube, 2.1; and Palmer apparatus, 1.0. On basis of weight of dust determined—impinger, 2.1; thimble, 1.5; sugar tube, 1.6; Palmer apparatus, 1.0.

These results, as well as others obtained in a comparative field study of the Palmer, konimeter, and impinger,[6] led to the selection of the impinger (Greenburg-Smith) by the Public Health Service as the standard device for dust sampling.

Several other instruments for the collection of dust have been developed since 1922. These are the Owens jet dust counter,[7] Drinker's modification of the electrical precipitator device,[8] and, more recently, Green has described a sedimentation cell method[9] and a thermal precipitator device,[10] which are being tried out in England. Of these four devices, the Owens and the electrical precipitator are the only ones

* The instruments and methods described in this paper are generally used in conducting research investigations for the purpose of evaluating the dust hazard in industry. Some are of the opinion that other instruments or methods of quantification of dust may be used for routine plant control of a dust hazard, provided of course that these simpler and quicker methods have been correlated with the standard procedure described in this paper.

which have been used to any great extent and for which data on performance are available. It may be safely stated that in so far as *present day practice* goes, the instruments finding common use for dust collection throughout the world are the impinger, konimeter, Owens, electrical precipitator, and the paper thimble. The others have either been discarded, as in the case of the Palmer and Anderson-Armspach dust determinator, or are still in the developmental stage, as is true of the sedimentation cell, thermal precipitator, and more recently, the electrostatic precipitator being developed by the Westinghouse research workers.*

THE SAMPLING OF INDUSTRIAL DUSTS

General Considerations—It is essential that any dust sampling instrument should be capable of collecting effectively dust of a size present in the industrial atmosphere. Recent studies by the author [11] indicate that industrial dusts are mainly from 0.5 to 5 microns in size, so that an instrument capable of collecting these sizes with a fairly high degree of efficiency should meet the present-day requirements. The range in dust concentrations encountered in industries is very great, depending, of course, on the industrial processes, the devices installed for mitigating the dust created, and the efficiency with which such devices function. For these reasons, an ideal instrument should be one capable of sampling with equal efficiency in both high and low dust concentrations. This factor calls for the prerequisite of a dust collecting medium which shall not add dust to any great degree to the dust in the sampled air. Furthermore, the collecting medium must be uniform in dust content, so that one or two control tests on this medium will be sufficient for a series of samples.

Since the dust content of industrial air is ever varying, it is essential that the dust sampling instrument be capable of collecting air in large quantities at a rapid rate, in order to obtain a representative picture of existing conditions. And, finally, the ideal instrument should be one that requires only a simple and fairly rapid method of analysis. Suffice it to say that an instrument designed for use in the field should embody all these principles, and, in addition, be light in weight, portable, and compact.

To recapitulate, the final selection of a dust sampling instrument for industrial use will depend on the collecting efficiency of the device, on its small errors in analysis, on its portability, and on the ease with which a sample, once obtained, may be analyzed.

Twelve years of experience with the impinger apparatus in this country by the U. S. Public Health Service,[12] by various research workers in our universities, insurance laboratories, and other interested governmental and industrial agencies, have shown this instrument to be of practical value as a device for the study of the industrial dust problem and one apparently filling the requirements set forth in the above discussion. Although the other devices, such as the konimeter, Owens, electrical precipitator, and paper thimble, are utilized from time to time in special problems, the impinger has been adopted quite universally in this country in hygienic dust investigations. For this reason a brief account of the construction and use of this device is presented herein. For details of the other instruments mentioned in this discussion the reader is referred to the original articles describing each, references to which have been given.

The Impinger Tube and Sampling Flask—The impinger apparatus consists essentially of two portions: First, a source of suf-

* Personal communication.

ficient suction to draw the air to be sampled through the sampling device; and second, the sampling device or impinger itself, which consists of a container and the impinger tube and plate. As a source of suction, an electrically driven and a compressed air driven apparatus have been designed. A hand driven apparatus developed at the U. S. Bureau of Mines has also been made. For details of construction of these various forms of suction devices the reader is referred to the original article.[12]

The impinger tube in the model of the apparatus described in *Public Health Bulletin No. 144* (p. 67) consisted of a piece of Pyrex glass tubing, drawn down to a tip with a 2.3 mm. orifice. To this tube a metal tripod and circular impinging plate were attached by means of a bronze split-sleeve clamp. The distance between the orifice and the upper surface of the plate was kept at 5 mm.

In practice, this impinger tube yielded satisfactory results. Nevertheless, it was felt that it would be preferable to eliminate the use of metal, particularly where acid or alkali was to be used as the collecting fluid. Accordingly, there was designed and constructed the all-glass impinger tube shown in Figure I, with circular glass impinger plate about 25 mm. in diameter, fixed by three

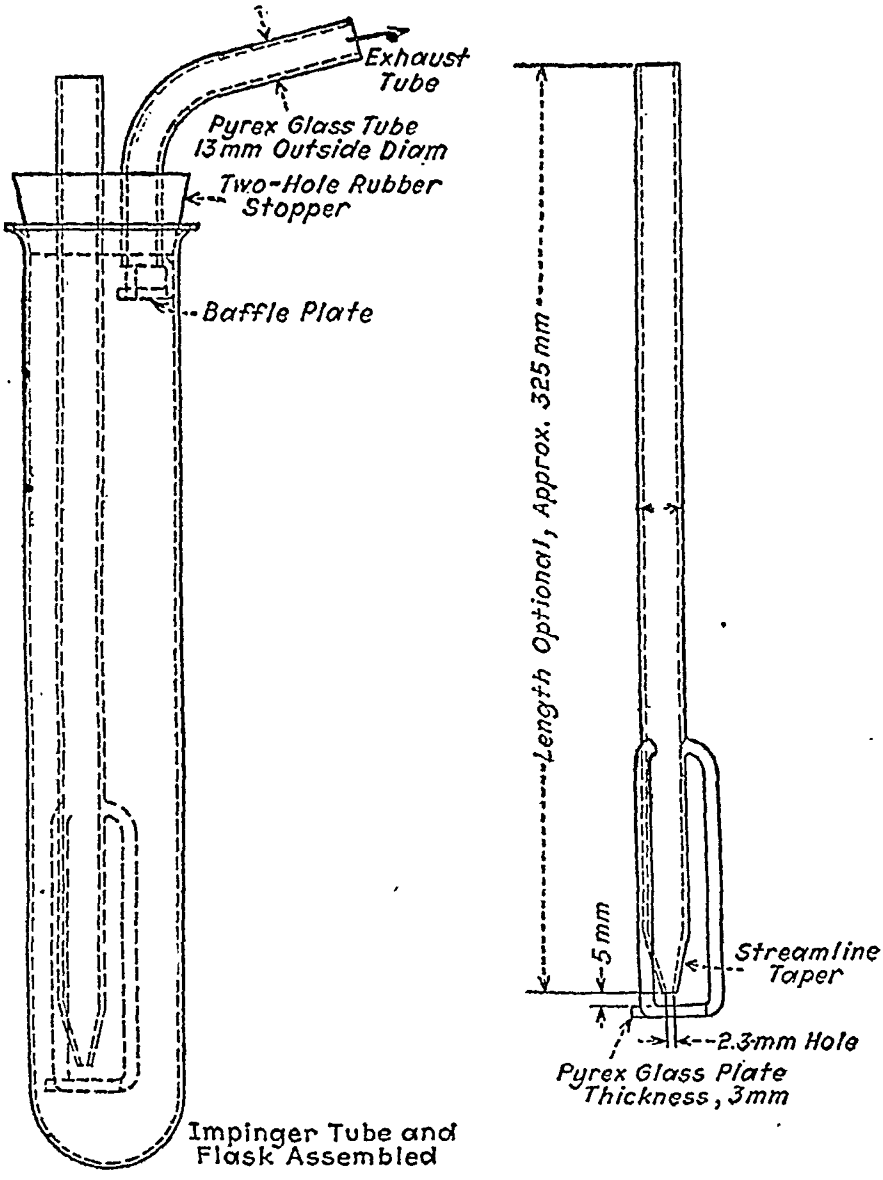

FIGURE I—DRAWING OF IMPINGER TUBE AND FLASK

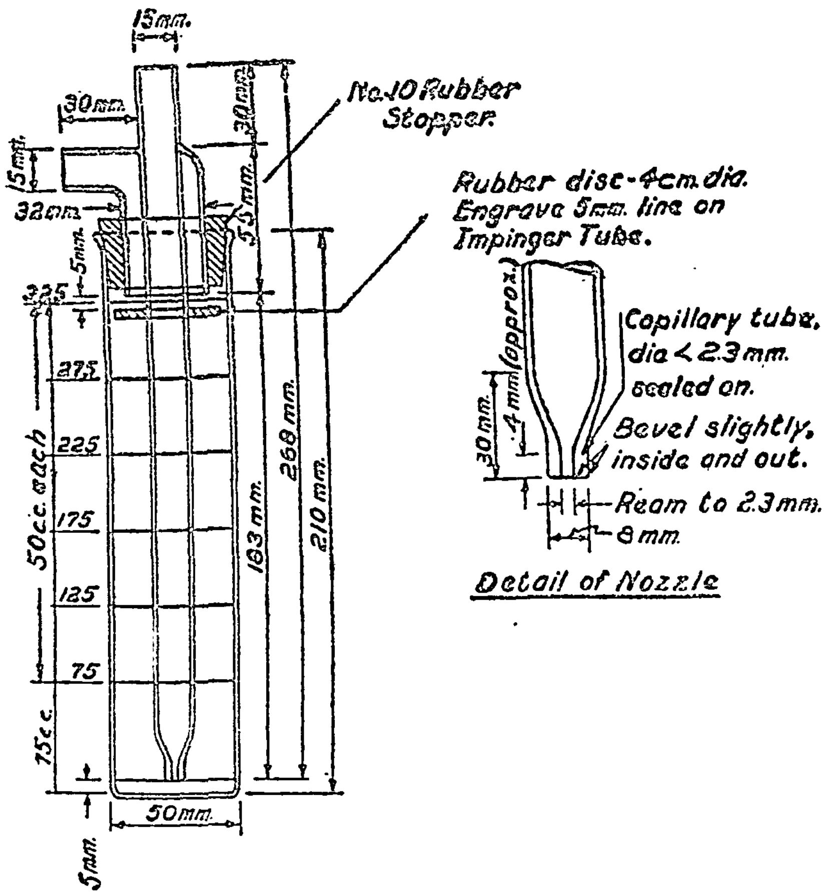

FIGURE II—DRAWING OF MODIFIED IMPINGER AND DETAIL OF NOZZLE, WITH CONSTRUCTION SPECIFICATIONS

supporting rods about 9 cm. long to the impinger tube at a distance of 5 mm. from the orifice. The tube was 13 mm. in outside diameter. Pyrex glass was used throughout. Tubes of this type have been employed without an undue amount of breakage.

A few modifications have been made in the impinger flask. Originally, a round 16 oz. glass bottle fitted with a 2 hole rubber stopper was used. A short time later a 500 c.c. Pyrex glass assay flask (wide-mouth conical Erlenmeyer type) was substituted, which proved to be very satisfactory.

In certain studies it was found desirable to obtain dust samples in the region of the mouth and nose of a worker in order to secure a more representative picture of the air actually breathed. For this purpose the flask shown in Figure I was designed.

A more compact and convenient impinger flask and nozzle has been recently developed for field use.[12a] The modifications in the design of the impinger have in no way altered the basic principle on which the instrument operates. Figure II shows the latest form of the impinger flask and nozzle.

The modified impinger does away with the glass impinging plate, utilizing the bottom of the flask for this purpose. The suction connection is combined with the inlet tube, thus simplifying the device still further. The essential portions of the device consist of a straight piece of Pyrex glass tubing 15 mm. in outside diameter and approximately 275 mm. in length. The tube is drawn down in stream-line form at its lower end, to a tip with a 2.3 mm. orifice. In sampling, this orifice is kept approximately 5 mm. from the bottom of the flask, a guide line on the flask indicating this distance. The flask is 50 mm. in diameter and 210 mm. in height, and requires a fluid (water) volume of only

75 c.c. to give the proper depth of immersion to the nozzle. An entrainment trap in the form of a rubber ring prevents the possible loss of the liquid (and dust) with the outgoing air.

Since the impingement distance in this instrument is not fixed, as in the previously described type, it was necessary to determine the limits within which this distance, as well as the angle of impingement from the perpendicular, varied. Studies conducted on these factors by the designers of this instrument showed that as regards the angle of impingement (using silica dust) one can have a maximum displacement of the nozzle without changing the efficiency obtained when the nozzle is in the vertical position. Also, it was found that the impinging distance can be varied from 2 to 12 mm. without impairing the efficiency against silica dust to any appreciable degree.

In taking dust samples the location of the sampling place, the time during which sampling is conducted, and the duration of sampling, are all chosen in an effort to obtain the data required by the study in progress. Obviously the requirements of the study under way govern the procedure to be employed.

The duration of the sampling period should be such as to yield a satisfactory suspension of dust for analysis, and is thus dependent on the concentration of dust in the atmosphere. Under the usual industrial conditions, samples of from 10 to 30 cu. ft. of air are sufficient to yield enough suspended dust for analysis. Since a sampling rate of 1 cu. ft. per minute is maintained, this will require a sampling period of from 10 to 30 minutes. A stop watch may be used to measure this period. After a sample is obtained, the impinger tube and flask are placed in a suitable carrying case for transport to the laboratory for subsequent analysis.

In Table I, a summary is presented giving the characteristics of the most commonly used dust sampling instruments.

It may be seen that all of the devices have a high sampling efficiency. Although each instrument has some disadvantages, experience has shown that there is a specific use for each device. The *impinger apparatus* can be employed for sampling in both high and low dust concentrations, and has the added advantage that the samples may usually be analyzed microscopically, chemically, or gravimetrically. In fact, it has also proved useful for sampling fumes and gases, provided certain precautions are exercised.[13, 14] The *electrical precipitator* finds its greatest field in the sampling of smoke and fumes. The *paper thimble* has been used very successfully for the sampling of radioactive dusts,[15] and is constantly employed in sampling organic dusts in connection with dust explosion prevention work. The *Owens jet dust counter* was primarily developed for the sampling of outdoor dusts and smoke, and is still used quite universally for this purpose. It is usually not practical for the sampling of industrial dusts of high concentration, the dust record being so thick as to make it impossible of enumeration. However, it has been used successfully for obtaining samples of industrial dusts for the purpose of particle size measurements.[11] The *konimeter* is very useful in obtaining rapid samples in moderate concentrations of aerial dusts. For quantities of 15 to 18 million particles or less per cu. ft. of air, it is very efficient and should find considerable use in control work and in preliminary studies. For such investigations the *Owens* and *konimeter* have the added advantage that they require no power for operation, are very small and compact, and do not need a highly skilled observer to obtain samples, although some skill is required in the enumeration of the dust records and in the interpretation of results.

Where the properties of an industrial dust, both chemical and physical, may vary from hour to hour at a given work position, due to the varying nature of the process, *e.g.*, periods of blasting, hard-heading, uneven ventilation, etc., additional precautions in sampling are obviously necessary.

So far this discussion has been

TABLE I

SUMMARY OF CHARACTERISTICS OF CERTAIN DUST-SAMPLING INSTRUMENTS

Instrument	*Characteristics*								
	Principle of operation	*Efficiency against industrial dusts (per cent)*	*Application*	*Method of quantification*	*Skill in quantification*	*Sampling skill*	*Volume of sample*	*Advantages of Instrument*	*Disadvantages of instrument*
Impinger......	Impingement.	98+.....	General......	Count, gravimetric, chemical	Considerable	Some....	Any amount; rate = 1 cu. ft. per minute	1. High sampling efficiency in either low or high dust concentrations 2. Sample can be quantificated by counting, weighing, or chemical analysis	1. Requires power for operation
Electrical precipitator	Electrical precipitation	100......	......do	......do......	....do....	Considerable	Any amount; rate = 10 to 50 liters a minute	1. High sampling efficiency in either low or high dust concentrations 2. Sample can be quantificated by counting, weighing, or chemical analysis 3. Large samples obtained rapidly	1. Requires electric power for operation 2. Some danger from high voltages
Paper thimble.	Filtration.....	100......	......do......	Gravimetric, chemical	Some....	Very little	Any amount; rate 1 to 2 cu. ft. per minute	1. High sampling efficiency 2. Samples large volumes rapidly 3. Laboratory technic requires only drying and weighing for most dusts 4. Samples may be kept indefinitely without deterioration	1. Samples cannot be counted 2. Drying of thimbles is a very slow process
Owens jet dust counter	Jet condensation	99+.....	Outdoor dust and for particle-size studies	Count........	....do....	....do....	50 to 1,000 c.c.	1. Light, simple, and quick to operate 2. High efficiency for atmospheric smoke 3. No power needed for operation 4. Laboratory technic requires only a microscope	1. Dust cannot be weighed or analyzed chemically 2. Obtains only "grab" samples due to small sampling volume 3. Impractical in high dust concentrations 4. Selective action; efficient only for dusts 2 microns or less
Konimeter.....	......do......	99+.....	For concentrations less than 18 million particles per cu. ft.	......do......	....do....	....do....	10 c.c........	1. Light, simple, and quick to operate 2. Efficiency high for moderate concentrations 3. No power needed for operation 4. Laboratory technic requires only a microscope	1. Dust cannot be weighed or analyzed chemically 2. Obtains only "grab" samples 3. Not practical in high dust concentrations; limited to 15 or 18 million particles, or less, per cu. ft.

limited to the collection of dusts of the type usually considered capable of producing fibrosis of the lungs or upper respiratory damage. For the collection of *poisonous dusts,* such as lead, the impinger or electrical precipitator has been found to be especially suited. In the case of the *impinger,* when used in sampling *lead dusts,* care should be taken that the sampling flask is of lead-free glass and that the distilled water also contains no traces of this substance. It is customary to run a blank for every 10 samples or so, which takes into account any lead present in the reagents. In sampling for minute traces of poisonous compounds, it is very essential that sufficiently large samples be obtained, enough to contain adequate amounts of the material for the particular method of analysis to be employed. It is apparent that both the impinger and electrical precipitator fulfil this requirement owing to their high air sampling rates. While the *paper thimble* has been used successfully for the collection of radioactive dusts, on the whole, the impinger and precipitator collect such dusts in a manner best suited for subsequent chemical analysis.

THE ANALYSIS OF INDUSTRIAL DUSTS

General Considerations—In the case of fibrosis producing dusts, the particle count appears at present to offer the best index of the hazardousness of a dusty operation. Obviously, the method of enumeration which is utilized should be governed by the consideration of the size of the dust which is of hygienic significance. To date, the relative significance of various sizes of dust particles in the production of lung fibrosis has not been satisfactorily established. However, we do know that the inhalation of certain industrial dusts has been found to be associated with definite injury to the pulmonary tissues. Hence, a knowledge of the size-frequency of these industrial dusts will, in a measure, determine the method of enumeration to be employed.

At present there are several sources of information which cast some light on this subject. One is the work of pathologists who have determined the size of dust particles recovered from silicotic lung tissue, another is the work done in connection with the retention of dusts in inhalation experiments, while additional information is presented by particle-size studies.

The work of the South Africans,[16, 17, 18] and Scheid of Germany,[19] indicate that most of the dust particles recovered from silicotic lungs of both humans and animals were between 1 and 3 μ in size, only about 13 per cent of the particles being less than 0.5 μ. Experiments on dust retention by Drinker and his associates,[20, 21, 22] as well as that of other investigators [23, 24] on the retention of dusts and fumes by man, also show that the finely divided suspensions of dust are retained but to a small extent in the lungs, usually from 15 to 25 per cent of the amounts inhaled. More recently, King and Dolan [25] have shown that extremely fine particles of quartz dust are rapidly dissolved in the mildly alkaline body fluids and are excreted in the urine. And finally, particle-size studies of industrial dusts in air [11] indicate that about 60 per cent of the dusts are from 1 to 3 μ in size and that only about 30 per cent of the particles are less than 1 μ.

From the foregoing information it is evident that in order to obtain a representative sample of industrial dust in air, one should employ an instrument capable of arresting, with a high degree of efficiency, all kinds of dusts, of sizes ranging from 0.5 to 5 μ at both high and low dust concentrations. The impinger apparatus fulfils this requirement.

The method of counting the dust particles in the samples should have

small analytical errors and should reveal only those significant particles present in industrial atmospheres. It should not be the aim to count all the dust particles present in the samples (which may be accomplished by either the use of high magnifications, dark-field illumination, or combinations of both), *e.g.*, it is necessary to differentiate between the dust content in normal air and industrial air. As has been indicated, this difference is apparently sharply marked in so far as the dust particles between 0.5 and 5 μ are concerned; but this difference would be masked and lost were there included in the determination the particles of ultra-microscopic size which are present in vast numbers in all air.

Enumeration of Impinger Samples—Owing to the solubility of most industrial dusts in water,[26] it is good practice to analyze impinger samples within 24 hours after collection. Dilution of the sample, if needed, may be made in the original sampling flask, to either 250 or 500 c.c. If further dilution is advisable, a 100 c.c. graduated flask may be employed. This dilution may conveniently be such that the number of particles counted in each microscope field is about 50 to 75. The contents of the flask are next thoroughly agitated in order to obtain a uniform suspension, and two portions of about 1 c.c. each are removed with a pipette so as just to fill, without bubbles, two Sedgwick-Rafter counting cells (see Figure III). The cells have been previously cleaned very carefully in order to remove any adventitious dust, and have been kept protected from dust particles by the cover slip.

In making dust counts an eyepiece micrometer known as a Whipple disk is employed (see Figure III). This disk has a large square engraved on it, covering a large part of the field, and this square is divided into 100 medium sized squares, one of these in turn being further subdivided into 25 very small squares. Using an ordinary microscope provided with a suitable eyepiece and objective, and fitted with an Abbé condenser, the proper tube length of the microscope is determined by calibration with a stage micrometer, so that the side of the large square of the eyepiece covers 1,000 μ (1 mm.). (A 7.5X eyepiece, 16 mm. objective, and a tube length of 178 mm. has been found to yield this result.) The large square of the eyepiece ruling, therefore, incloses the dust in an area of 1 sq. mm.; and since the cell is 1 mm. deep, all the dust suspended in 1 cu. mm. of the water is under the ruled field. This examination is accomplished by raising and lowering the lens system so as to focus throughout the entire depth of the cell. As a source of illumination, an ordinary small electric microscope lamp may be employed. In order to provide a high degree of visibility for refractile objects it is best to lower the Abbé condenser system below the usual focusing point and to restrict the opening in the iris diaphragm.

The dust is allowed to settle for 20 to 30 minutes before counting is done. In general, only particles less than 10 μ in diameter are counted. The inclusion of particles larger than 10 μ in the specimen would make but little change in the total count. The average diameter of a particle for the purpose of this exclusion is judged by inspection. In practice it is necessary to count the dust in only one-quarter of each ruled field, the entire field having been examined for uniformity. Such counts on 5 fields, so dispersed as to be representative, are made on each of the two Sedgwick-Rafter cells. These 10 counts are averaged, but this average is not to be taken as the final count until a corresponding con-

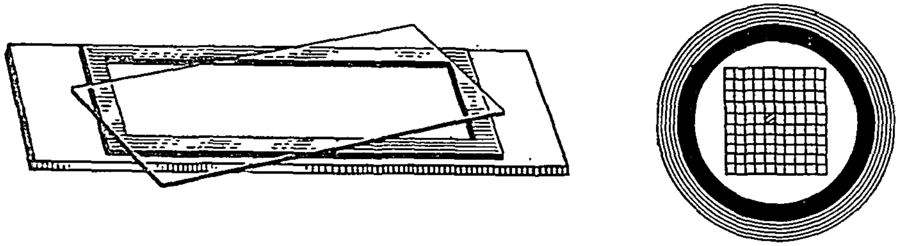

FIGURE III

trol count has been subtracted. In all cases a sampling flask which is handled in the plant, but through which no air has been aspirated, is used as the control for the particular series of samples taken in that plant on that particular day, and counts are made on this control fluid in the same manner as on the fluid through which the air sample has been impinged. The control sample takes into consideration any dust which may be present in the eyepiece micrometer, in the lenses of the microscope, in the Sedgwick-Rafter counting cell, and in the sampling fluid itself. From the average gross count obtained on the impinger sample, the average control count is to be subtracted to give the average net count per ¼-microscopic field.

The average net count per ¼-microscopic field is multiplied by 4 to yield the average count in the total field. Since the Sedgwick-Rafter cell is 1 mm. deep, this figure represents the number of particles in a cu. mm. of the diluted sample. This value is multiplied by 1,000 to give the count per c.c. of sample, and again by the total number of c.c. of fluid to which the original specimen was diluted. This product is divided by the number of cu. ft. of air sampled. In summary, the number of particles per cu. ft. of air = average net count per ¼ field times a factor, where the factor =

$$\frac{4 \times 1{,}000 \times \text{total volume of diluted sample in c.c.}}{\text{Volume of air sampled in cu. ft.}}$$

The method of dust counting presented herein is capable of including dust particles as small as 0.7 μ.[10, 11, 27] * From data presented earlier on the size-frequency of industrial dusts, it is apparent that this method is capable of disclosing about 85 per cent of the dust particles collected by the impinger apparatus. The small percentage of dust this method fails to reveal is considered negligible, when one takes into consideration the simplicity of the method, the fact that results may be checked by trained observers, and that it is one of practical application since, in the numerous dust studies conducted by the U. S. Public Health Service on the health of workers in dusty trades, high correlations were obtained between the intensity of exposure to dust and the degree of lung damage among the workers.

* Some of the members of the committee are doubtful whether dust particles under 1 μ (and possibly 2 μ) can be seen by means of a light field method of illumination. Hence these resort to a dark field microscopic system almost exclusively, and check this from time to time with the standard light field method.

THE DETERMINATION OF THE CHARACTER AND COMPOSITION OF INDUSTRIAL DUSTS

Size of Dusts—So far as the size of the dust particles is concerned, it is apparent that in order for any given dust to produce injury to the lungs it must gain access to the parenchyma of the lungs, the site where the harmful effects of the dust take place. It has already been shown that not all of the particles of inhaled dust gain access or are retained by the human lungs. For these reasons it is of some value to determine the size of the dust present in the industrial atmosphere.

It has also been demonstrated that particles of a size greater than 10 μ in longest dimension are very seldom found in the lungs, due partly to the fact that the number of such particles, in industrial air, is comparatively small when particles in the lower size range are considered. Due to gravity, which causes rapid settling of suspensions, and due to the protective action of the upper respiratory tract, these larger particles do not penetrate to the terminal portions of the lungs. Hence, it is obvious that attention be directed to those particles which are less than 10 μ in longest dimension.

The likely procedure for the sampling of atmospheric dusts for particle-size studies would be to employ the same instrument utilized in sampling dust for quantitation.

In the past, the Owens jet dust counter has been employed extensively for such investigations, although of late impinger samples have been utilized for this purpose; comparative studies of the two instruments yield practically identical results. The Owens jet dust counter obtains a sample of dust from the air in more or less unaltered con-

dition, since with this device the atmospheric dust is directly projected on a naked cover-slip. Moreover, the instrument is small, compact, requires only hand power, and samples are obtained quickly and easily without needing much skill of operation. Once these samples have been obtained and properly mounted, the dust particles may be measured by the use of a filar ocular micrometer at a magnification of 1,000 diameters (oil immersion objective).[28] The horizontal diameter of at least 200 dust particles in several representative fields are measured for each sample. With this magnification it was found possible to measure particles as small as 0.5 μ in size, while particles smaller than this size are easily distinguished at this magnification and their presence recorded.

Photographic methods have been suggested and used for measuring dust particles, but in order to obtain good photomicrographs it is essential that the dust particles be in one plane, free from Brownian movement and well dispersed. Since industrial dusts are seldom of a uniform size it is difficult to fulfil the first requirement. Comparisons have been made between the results obtained with the direct filar measurements and the photographic method on typical industrial dust samples. This comparison demonstrated that the simpler and less expensive filar method yielded practically the same results. Since the filar method fulfils the requirements of this problem it is suggested for use in such studies, unless permanent records are wanted, where photographs might well meet the requirement.

Composition of Industrial Dusts—The methods used in determining the composition of certain poisonous dusts, such as lead compounds, are amply discussed in the numerous publications dealing with these problems. Concerning the so-called fibrosis producing dusts, the work of the past 20 years on the problem of dust inhalation has demonstrated that, in general, the degree of health hazard associated with the inhalation of any dust, all other factors remaining constant, is dependent upon the mineralogical composition of the dust. For example, it is now established that the inhalation of certain types of dust, such as granite dust[29] may, in time, produce fibrosis of the lungs, frequently associated with tuberculosis. In other cases exposure to dust may result in the production of a far lesser degree of fibrosis without subsequent tuberculosis; this is true of cement dust.[30] And finally, there are certain types of dusts which produce little lung fibrosis, as typified by marble dust.[31] In general it has been found that those dusts which are high in quartz content are the ones which most readily produce a disabling fibrosis of the lungs.

The question of ultimate importance of silicates or combined silica (silica, sericite, talc, etc.) in the production of pathology is at present undergoing extensive study, but it is trusted that the methods of sampling and counting, enumeration, and sizing of dust particles above described will be found to be adequate for all injurious forms of mineral and other industrial dusts. Should it be ultimately shown that dusts less than 0.5 μ in diameter are a serious factor in the production of disease, resort may have to be made to the more refined methods of estimation referred to, and possible new methods devised.

Analytical methods for determining the chemical composition of some inorganic atmospheric dusts are referred to by W. A. Cook in another section of this report. It is to be noted, however, that a chemical analysis of a mineral dust will not disclose the various percentages of minerals existing in the dust. For example, a chemical analysis of granite dust will not reveal the percentage of quartz present in the dust, but will only tell the analyst the total silica, combined and uncombined. Hence, the close relationship

of the chemist, mineralogist, and petrographer to the situation must be kept constantly in mind. It is not considered, however, within the scope of this report to go into this feature.

Advisability of Routine Laboratory Examination of Food Handlers

YOUR Committee on the Advisability of Routine Laboratory Examination of Food Handlers made a progress report in 1934 (see *Year Book 1934–1935,* page 113) on two aspects of the food handler problem, *i.e.,* an evaluation of the recommendations of health executives and the significance of food handlers as a source of infection. The recommendations of the Surgeon General's Advisory Board on Milk Ordinance were cited. These recommendations are part of the Milk Ordinance and Code of the U. S. Public Health Service. The committee appreciates that these regulations are based upon an extensive study of the milk handler problem. Mr. Abel of the Advisory Board made a careful survey of the food handlers' problem in Alabama. In his recommendations solicited by the committee in 1933, he made a valuable suggestion which the chairman had hoped to follow up; namely, a study of the use of dyes for determining the authenticity of specimens of feces in the search for typhoid carriers. There has been no opportunity to make this investigation.

Special investigations have been made by members of the committee: Mr. Mickel, *et al.,* on the detection of carriers among food handlers (*A.J.P.H.* 24:493, 1934) and laboratory examinations of milk handlers (*A.J.P.H.* 25:557, 1935); Dr. Gilbert, on the practical limitations of examinations of specimens collected without regard to clinical history or epidemiological evidence (*A.J.P.H.* 24:193, 1934); Dr. MacNabb, on control measures in the municipalities of the Province of Ontario and routine examinations of food handlers in selected groups.

During the year a study of the incidence of *Beta hemolytic streptococci* from throat cultures of milk handlers was made by the Connecticut Department of Health and Yale University School of Medicine. The results of these studies will be reported in the *American Journal of Public Health.*

Routine health examinations—Although not strictly within the province of this committee, consideration of the control measures recommended by the health executives has been continued during the year. The New York City Department of Health rescinded the section of the Sanitary Code which provides for the yearly health examinations of food handlers. The control measure had been in effect for about twenty years. "The plan," quoting from Dr. Rice's report, "was adopted in 1915 in order to impress upon food handlers the rôle played by infection in the spread of communicable diseases and to encourage the practice of periodical health examinations." It is a significant fact that routine examinations of food handlers continue to be inaugurated by health executives for the same or similar reasons. Such examinations may include routine laboratory examinations of all applicants or only laboratory examinations when indicated by the medical examiner.

Significance of food handlers as sources of infection—In order to study further the significance of food han-

dlers as sources of infections, a questionnaire was sent to the state epidemiologists requesting information regarding the number, the infection, the source and mode of food-borne epidemics during 1930–1934 inclusive, and the number of cases and deaths. The committee wishes to thank the epidemiologists for their splendid response. In a number of instances, it meant special effort to accumulate the information.

In a surprising number of states, the records were incomplete or information unavailable. From an analysis by the committee of the replies, the following conclusions were drawn:

1. That many of the state departments of health are inadequately organized, not only for detecting outbreaks of food-borne infections, but also for placing them in their proper categories.
2. That the most important single food which may become a disease vector is raw milk.
3. That wherever a state department of health is well organized and proper search is made, a considerable number of outbreaks are found in which food is the vehicle of transmission.
4. That the number of these outbreaks, even in the imperfect manner in which they have been reported, is sufficient evidence to make the inspection of food handlers by some method or other seem worth while.

EVALUATION OF LABORATORY EXAMINATIONS

Laboratory examinations and tests are obviously for the detection of carriers and mild cases or for the confirmation of clinical findings. Laboratory examination as an aid to diagnosis needs no discussion. The need for laboratory examinations supplementing epidemiological investigations of food-borne outbreaks is recognized as essential. The value of routine laboratory examinations has been questioned, however.

The discussion of routine laboratory examinations for detection of carriers follows:

The index to the typhoid carrier is the typhoid case and a careful follow-up of convalescents and contacts would concentrate effort at the source of danger and eliminate the necessity of examining all food handlers for a possible carrier. In illustration of this, the experience of New York City is significant. Since 1915, a total of 565 typhoid carriers was discovered in New York City. Of this number, 308 were discovered as the result of epidemiological investigations made in connection with cases of typhoid fever, and 227 were discovered through stool examinations of patients after convalescence. In contrast to this, out of three and one-half million routine annual examinations made of food handlers during the past 18 years, only 30 typhoid carriers were discovered. This is less than one out of each 100,000 food handlers examined.

The specimens most frequently submitted to the laboratory from food handlers are for the control of enteric infections. These may be either blood serum for the Widal reaction or feces for *B. typhosus*, *B. enteritidis*, etc. The Widal has a limited value for it has been shown that carriers occasionally have no demonstrable agglutinins in the blood stream. The value of the examination of feces depends upon the number of specimens submitted and authenticity of the specimen. Bile is the most satisfactory specimen for the identification of a typhoid carrier. Laboratory examinations of routine specimens from food handlers are not recommended, except from raw milk handlers. However, routine examinations of raw milk handlers at regular intervals without other control measures do not render the supply of raw milk safe.

Septic sore throat and scarlet fever—Milk-borne outbreaks of septic sore throat and scarlet fever are of great

importance, but routine throat swab examinations for the detection of carriers are not practical. The wide distribution of hemolytic streptococci, and the multiplicity of strains makes classification necessary. The classification of hemolytic streptococci is a difficult procedure, involving time and special technic. Hence, the examination of throat swabs for identification of hemolytic streptococci is not recommended except under epidemiological direction.

Diphtheria—Diphtheria bacilli are of little significance in food-borne outbreaks. The detection of carriers has no practical value.

Tuberculosis—Food-borne tuberculosis is confined almost entirely to the bovine type as far as we know. Laboratory tests are not as efficient for diagnosing missed cases as physical examinations in conjunction with the skin test and X-ray.

Amebic dysentery—Carriers of *Entameba histolytica* still present some unsolved problems. How many persons contract the disease from another is not clear. The laboratory examination must be made by an experienced bacteriologist and on carefully collected specimens. The detection of *Entameba histolytica* in chronic amebiasis (the carrier) usually involves the examinations of scrapings obtained at sigmoidoscopy. Hence, laboratory examinations of specimens from food handlers are not recommended except under epidemiological direction.

It is felt by the committee that the indiscriminate collection and examination of specimens from food handlers are undesirable, and that such examinations should be made only where called for by epidemiological or clinical findings.

Aspects of Veterinary Public Health

VETERINARIANS who become peculiarly involved with the work of public health usually will be found active in: (1) Meat inspection, (2) Milk inspection, (3) Bovine tuberculosis control, (4) Biologic production, (5) Immunology, (6) Bacteriology, (7) Serology, (8) Rabies control, and (9) Academic.

The veterinarian in general practice only contacts such specializations, casually. Tuberculosis, rabies, and brucelliasis constitute material of public health significance most frequently published in American veterinary journals. In such articles, the rule is that the public health aspects are incidental to more pertinent veterinary problems.

Under these circumstances, the veterinarian in public health has specialized away from his fundamental training for general practice and has become absorbed in logical groups or sections which include: (a) Laboratory Section, (b) Food and Nutrition Section, (c) Public Health Education Section, and (d) Instances of veterinarians who are health officers.

The loss of professional identity is not different from the case of the doctor of human medicine who has entered sections specializing in branches of public health. We can conceive that the creation of a separate section for veterinarians would only result in confusion, since the actual functions within the profession are so varied in actual health department practice.

An expression of opinion from the majority of veterinarians in public health work has so far been impossible. This is due to the fact that there is not available a registry of such men. We believe this should be one of the first endeavors of a committee during the coming year. Such a listing, with notations of the type of work engaged in, would alter the present obscure viewpoint to one of a more definite perspective.

Letters have been received from Missouri, Pennsylvania, New York, Illinois, Iowa, and Canada. Trends of such letters include such statements as:

1. " It does not occur to me that the Sections of the American Public Health Association should be set up with a view of giving any particular profession recognition."
2. " A section on veterinary public health would probably not be a flourishing one at least for some years "
3. " ' Veterinary ' is objectionable from the standpoint of linking such an activity directly with the practising veterinarian. We do not have physicians' public health sections."
4. " I do not consider it advisable to form a separate veterinary public health section immediately."
5. In Canada: " I do not think that there is any desire with us to form a separate section. . . . "
6. " . . . a section for veterinarians would scarcely seem in accord with the present policies any more than would a section for physicians."
7. " . . . it often happens that a veterinarian is the one most competent to discuss human infections of animal origin. Papers of this kind would be of general medical and bacteriological interest, and it does not seem to me they should be shut off by themselves in any way from the (Laboratory) Section."

Those favoring a separate section were few in number. Arguments favoring such a break from the Laboratory Section, etc., fundamentally reflect the feeling that the veterinary profession

does not obtain the recognition it should in the good work done. The following excerpt from a letter of December 14, 1934, was the result of careful checking with associates before the chairman expressed his general conclusion:

"Those who teach Veterinary Hygiene in veterinary schools are very anxious to make public health officials aware of the fitness of the veterinary graduate to supervise milk and meat production. Therefore, I am voicing the desire of that body when I support those who believe that a separate section of the American Public Health Association for the consideration of the problems of food inspection should be formed."

Again, we can give voice to a strictly personal opinion as chairman of this committee. Why not inaugurate in the pages of the *Journal* a roster of veterinarians who are members of the American Public Health Association? Why not list the Fellows and the Associates? Many familiar names would be recognized in such a listing—names of workers who produced as "sanitarians" work of moment and importance to our general efforts in public service. An abstract section for articles pertinent to public health produced by veterinarians would remove some of the obscurity to the profession without in any way divorcing us from our chosen Sections.

The majority should formulate an opinion. For that reason this committee cannot offer more than a progress report. Once a roster of veterinarians is obtained, then can they be generally circularized, and a survey by questionnaire should result in a decision, during the year, as to the desire or lack of a desire for a separate section.

R. V. STONE, *Chairman*

Resistance of Micrococci to Pasteurization*

ONE of the most commonly encountered groups of organisms in milk and other dairy products is the group of micrococci. The public health significance of this group, its effect on the chemical changes in the milk, and its relation to the sanitary production of milk, has been discussed by a number of workers. The results of these discussions based upon research have not been concordant in their conclusions. One of the difficulties of obtaining more concrete data with respect to the micrococci is due largely to the variability of individual strains with respect to their reaction to external influences, particularly heat. It must not be overlooked that other variable factors as age of culture, reaction of media, etc., may affect the heat resistance of this group.

The public health significance of the micrococci still remains a problem due to the variability with which toxins are produced by certain species of this particular genus. It has been found that the orange types (*Micrococcus aureus*) are more given to the production of toxins than any other of the species. However, there appears to be a variation also in this respect due probably to the type of medium and the source of nitrogen provided these organisms. For this reason, it is difficult to determine definitely the types which are of public health significance from this particular standpoint.

The ability of the micrococci to resist heat, particularly the pasteurization temperature, *viz.*, 145° F. for 30 minutes, is also a variable character. A study of the plates made from pasteurized milk in routine control work will generally reveal the presence of a certain number of micrococci. If the plates are allowed to stand at room temperature for several days, the micrococcus colonies frequently become more readily recognizable because of the development of lemon yellow or orange pigments. None of the species of this genus have been found to be thermophilic, *i.e.*, they will not grow at 55° C. (131° F.).

It is of interest to note that although these organisms are very common in milk and dairy products, only meager data are available as to their ability to resist 145° for 30 minutes.

Sternberg (1887) and Van Geuns (1889) were among the first to study definitely the heat resistance of the micrococci. The latter found that the yellow types in some cases were more resistant than the strains which failed to produce pigment. He also noted that certain strains were completely killed at 140° F. for 30 minutes, while other cultures resisted 145° F. when held for the same length of time. Dyar (1895) found a species of micrococcus which resisted 212° F.

From the standpoint of pasteurization, the work of Russell and Hastings (1902), as well as that of Orla-Jensen (1919), indicates that there are definite species of micrococci which will resist ordinary pasteurization temperatures. Russell and Hastings found a lemon yellow micrococcus which withstood pasteurization and required 169° F. to be killed. Orla-Jensen reports that

* Report of the Committee on Milk Pasteurization Studies of the Laboratory Section.

certain of the white liquefying types will resist 145° to 165° F. for 15 minutes.

More recent work has shown that the yellow type of micrococci are more resistant to pasteurization temperatures than any of the other species. Robertson (1927), Hammer and Trout (1928), Hucker (1928), Eglinton and Yale (1931), and more recently Myers,* have found that the yellow or orange types are resistant to a temperature of 145° F. for 30 minutes.

The members of this genus are more heat resistant than any other of the generally encountered non-spore-bearing organisms. Since many species of this genus have thermal death times considerably greater than 30 minutes at 143.5° F., they are not killed by efficient pasteurization. Dotterrer (1923) was one of the first to point out that where producers bring in milk with a high bacterial count, the counts from the pasteurized milk may also be high because large numbers of bacteria, usually micrococci, may be so heat resistant that they are not killed by the pasteurization. Dotterrer, Myers, and Phelan * have made extensive use of routine laboratory tests to locate producers whose milk is contaminated with heat resistant organisms. It is possible also by carefully controlled laboratory

pasteurization in connection with commercial plant pasteurization to determine whether high colony counts on the pasteurized milk are due to the presence of large numbers of heat resistant bacteria or to defective or inadequate commercial pasteurization.

A study of the micrococci resisting pasteurization may throw considerable light on the conditions under which the milk was produced and pasteurized. In most instances the micrococci are inhabitants in the normal udder and, according to Breed (1928), the normal micrococcus flora of the udder may be several thousands per c.c. without any evidence of an infection being present. Among these udder types are to be found the yellow or the most resistant varieties of micrococci. For this reason, when commercial pasteurization is carried out effectively as demonstrated by comparison of pasteurization in the laboratory of small samples with samples secured from the plant pasteurizer, and heat resistant micrococci found still to be present, the source of these organisms may be the bovine udder.

However, Wickham and Widmer (1931) feel that thermoduric organisms are derived from improper sterilization of the utensils and that their presence should be considered when quality is used as a basis for payment to producers. They feel that shippers who deliver milk at the pasteurizing plant free from thermoduric organisms should be given preference over shippers furnishing milk that contains large numbers of heat resistant bacteria.

When micrococci are present in pasteurized milk they may be of the heat resistant types which will resist 145° F. for 30 minutes (Table I), or they may be of the border-line heat resistant varieties which survive pasteurization if this process is not carried out efficiently.

Coördinating Committee on Standard Methods

THE membership of the Coördinating Committee remains exactly as it was constituted at the Indianapolis meeting. The selections made then were so fortunate that no change has been contemplated. Each of the Chairmen of the three Standard Methods committees has put into his work that combination of sincerity, devotion, and enthusiasm which is so rare and precious an asset to any organization. The keen interest of the Section Secretary in every plan and development has been a constant source of constructive suggestion. As their respective reports will show, our committees are making the progress the Association demands of us.

The Water committee, under the Chairmanship of Dr. John F. Norton, has, during the year, completed an important coöperative investigation of various types of selective culture media that had been suggested for use in the bacteriological tests. In addition certain chemical factors have been carefully studied. The results and recommendations will be presented in detail at this meeting.

The Committee on Dairy and Food Products, under the Chairmanship of Dr. Robert Breed, has been engaged in fundamental studies based chiefly upon the composition of the culture medium and the temperature of incubation used in the bacteriological examination of milk. The results of their work are so convincing that there is no doubt that the new methods elaborated should be adopted. This will involve changes in significance of numerical results and their interpretation and may even require amendment of milk codes and regulations. Even with the fundamental support of accurate laboratory demonstration such innovations will not gain general acceptance by mandate alone. Their adoption into current laboratory practice will result only from a persistent and carefully planned campaign of education, continued until those most concerned themselves demand the change.

It is fortunate that we have, in the chairman of our milk committee, a man competent, not only to recognize and develop more accurate laboratory analytical procedures but one also with the experience and judgment which enable him to organize the coöperative publicity required to bring about, in the most effective manner, general utilization of the new methods developed by his committee.

Accomplishments of the committee during the year will be described in detail by Dr. Breed and his referees. Their reports of fundamental studies will not, however, concern the milk program alone. Equally interesting and important progress has been made in the work upon the "Sanitary Oyster."

The reports already published by referees of Dr. W. D. Stovall's Committee on Diagnostic Procedures and Reagents illustrate the type of work that is being done by that group. The field being covered by this committee comprises all the routine technical procedures of the public health laboratory

(except, of course, those concerned with water and milk). The progress made during the year will be demonstrated by the contributions to be read at this meeting. It is predicted confidently that when Dr. Stovall has collected the approved reports of his referees he will have produced a laboratory manual equal in every way to the best publications of our Association.

As a result of the continuing policy of constant investigation and revision by referees who are outstanding in their special fields, our Standard Methods Committee reports maintain a unique position in laboratory literature.

In the chairman's report for last year it seemed necessary to refer to certain misunderstandings concerning the scope of our standard methods work. This year it seems unnecessary to refer to such discussions but merely to observe that there have been none.

At a meeting in Chicago, last December, Dr. Stovall asked several of the referees of his committee who were present to meet him at an informal conference. The discussion of work in which there was common interest proved to be most stimulating. As a result of that experience it has been decided to bring all Laboratory Section Standard Methods Committee members together at a dinner meeting this year. The purpose, of course, is chiefly that of making those who are creating public health laboratory history well acquainted with one another. It is not unlikely that this dinner conference will become one of the established features of subsequent Annual Meetings of the Association.

The only recommendation I have to make concerns the appointment of a new committee. Studies are being reported with greater frequency concerning the variable reactions of laboratory animals to experimental infection and to antigenic substances. There is already in the literature abundant information concerning the relative resistance of the species to infection and concerning differences in strains or breeds of the same animal species. Often we find it advisable to breed our own animals in order to have a pure line for special work. The ages and weights of animals most suited to the particular purpose are often exceedingly important. There are matters concerning the general care of laboratory animals which are not common knowledge. The same may be said concerning normal blood counts, anatomy, and physiology, as well as autopsy methods. Such information may be difficult to find at the time it is most needed and may require considerable literary research. We need to have it collected into a single volume by a group of referees best qualified and working together as our other Standard Methods Committees have been doing. It is recommended, therefore, to the council of the Laboratory Section that, in accordance with the rules and regulations governing Standard Methods Committees, a new committee be formed to be known as the "Standard Methods Committee on the Biology of Laboratory Animals," of the Laboratory Section.

As Chairman of the Coördinating Committee, I can express nothing but the deepest gratitude to all those with whom I have been in correspondence during the past year. They have made my labors very light—I have been on the receiving end throughout—and they have created a most optimistic belief in a productive future for our Laboratory Section.

Examination of Dairy and Food Products*

Present Status of the Report on Standard Methods for the Examination of Dairy Products—One of the most important activities of your committee during the past year has been the maintenance of contacts with other committees, sections, and associations interested in the development of laboratory methods for the examination of dairy products. There are so many of these that only the most important can be mentioned. Contact has been maintained with the work of the Association of Official Agricultural Chemists in the field of chemical analysis of dairy products and they have been urged to broaden the scope of their work to include methods for the detection of nutritionally important mineral elements in dairy products. Arrangements to include methods for the bioassay of milk have been made through the Food and Nutrition Section of this Association, and a report on these methods is to be given during the symposium on Standard Methods for the Examination of Dairy Products.

Through coöperation with the Committee on Bacteriological Methods of the International Association of Dairy and Milk Inspectors, a questionnaire has been distributed on the use now being made of the tentative Standard Methods for the Examination of Ice Cream. A report on this matter is to be made before the latter association at its annual meeting which follows immediately after the meeting of the American Public Health Association. At the same time, the chairman of your committee is to make a report on the efforts that are being made to bring about an international standardization of laboratory methods in the dairy field. International activities have led to the organization of a symposium on this subject which your chairman has been asked to open before the Second International Congress for Microbiology that is to be held in London in July, 1936.

A report on the work of the Standard Methods Committee for the Examination of Dairy and Food Products has also been given during the year before the Laboratory Section of the International Association of Milk Dealers, and before the American Dairy Science Association. Contact has also been established with the Committee on Standard Methods for Milk Analysis of the Canadian Public Health Association, and Committees on Research of the Ice Cream Manufacturers' Association, and of the American Association of Creamery Butter Manufacturers.

The secretarial assistance provided by the American Public Health Association has permitted us to maintain an active address list of the nearly 1,000 laboratories in the United States and Canada that utilize standard laboratory procedures for the examination of dairy products. Four reports and the questionnaire referred to above have been distributed to these laboratories during the past year.

Because of the demand for the inclusion of methods of making bacterial

* Report of the Standard Methods Committee.

counts for ice cream and for the inclusion of methods for the detection and microscopic examination of sediment in heavy cream and butter, and for making counts of yeasts and molds in butter, it is planned to broaden the scope of the next report. It has been suggested that the next edition should be called Standard Methods for the Examination of Dairy Products rather than to use the older title of Standard Methods of Milk Analysis. An Associate Referee to cover ice cream methods was appointed some time ago and Dr. E. H. Parfitt has recently been appointed Associate Referee to cover methods for the examination of butter. Their activities in this field are to be limited, as are the activities of the committee, to the development of methods that are useful in official control work.

During the year, several investigations that have a bearing on standard laboratory methods for the examination of dairy products have been completed under the general supervision of your committee, or by independent workers. The most important of these studies that are known to your committee are—

1. A study of the usefulness of samples of milk taken for bacterial analyses from weigh vats at receiving stations. (To be discussed at the meeting of the Laboratory Section of International Association of Milk Dealers.)
2. Further studies on the composition of standard agar.
3. Further studies on the optimum temperature of incubation to use in case an improved agar is selected.
4. Studies on methods of improving the standardization of the methylene blue reduction technic.
5. Studies on the efficiency of the tentative methods outlined for detecting organisms of the colon group in dairy products. (Reports on studies mentioned under 2, 3, 4 and 5 are to be reported at the symposium on Standard Methods for the Examination of Dairy Products.)
6. Studies on the significance of the presence of organisms of the colon group in samples of raw milk that are not more than 4 hours old. (To be reported at the meeting of the International Association of Dairy and Milk Inspectors.)
7. Studies on the usefulness of the colon test as a means of detecting inefficient pasteurization. (To be reported at the New York State Dairy and Milk Inspectors' Association, and at the International Association of Milk Dealers.)

It is expected that the next edition of the *Standard Methods for the Examination of Dairy Products* will utilize the conclusions reached in these or subsequent investigations in the same field.

The reports by Dr. Hagan on methods of detecting tubercle bacilli in milk and by Dr. Huddleson on methods of detecting Brucella organisms in milk (*Year Book, 1934–1935*) have been favorably received and it is planned to include these with slight modifications in the next edition of the milk report.

Present Status of the Shellfish Report—The revision of the 1922 first edition of Standard Methods for the Examination of Shellfish, prepared by a Committee of which the late Professor Gorham was chairman, was approved by the Laboratory Section at Pasadena in September, and by the Committee on Research and Standards of the Association in December, 1934, for use as a basis for further revision. This second edition of the 1922 report has not been published, but has been distributed in mimeographed form with a questionnaire to all persons in the United States and Canada believed to be interested in a revision of methods. A conference of interested persons was held in Washington, D. C., at which a compilation was made of answers to a questionnaire sent out by Dr. C. A. Perry. A symposium on this general subject has been arranged for the Milwaukee meeting and this compilation will form an important part of the progress report to be given at that time.

General—The work of the committee has been greatly facilitated by the pro-

vision made by officers of the Association of funds which have permitted the holding of a conference on Dairy Products Methods at Geneva, N. Y., April 8, 1935, and a conference on the Shellfish Report held jointly with representatives of the Food and Nutrition and Public Health Engineering Sections at Washington, D. C., April 18, 1935. The first printing of 2,000 copies of the Sixth Edition of the Milk Report was sold out during the year and the report was reprinted in an edition of 3,000 copies. This edition is expected to last until 1937 at which time it is planned to present the manuscript of a new edition for approval by the Section and the Association.

Examination of Shellfish for Fecal Pollution*

A Revised Bacteriological Procedure

THE present method for bacteriological examination of oysters for fecal pollution has been severely criticised by many of those who have given extensive and studious consideration to it. This method was the outgrowth of studies begun by a committee of the American Public Health Association and reported on in 1912 and 1916. The method was finally adopted by the Laboratory Section at San Francisco in September, 1920, and published in Volume 21 of the official JOURNAL of the Association in 1922. Minor changes, particularly in the phraseology of the method, were made by Professor Gorham at Washington in 1922, but these changes did not make the method any more suitable for its primary purpose of measuring fecal pollution and did not, consequently, satisfy the growing criticism.

A mimeographed revision of the 1922 standard procedure was distributed with a questionnaire on February 10, 1935. Seventy copies of the method and questionnaire were sent to all persons in the United States and Canada known to be interested. Fifty-three of these were sent to individuals in 40 different laboratories and to 17 other persons thought to be interested in an official method for the examination of shellfish. Twenty-five questionnaires were returned with answers to some or all of the questions while 10 persons sent replies by letter who did not consider themselves qualified to answer the questions. It may be assumed, therefore, that the replies to this questionnaire represent the attitude of those who have had most experience with the present standard method. The replies to the questionnaire were compiled in as brief a manner as possible as a basis for further criticism.

A conference of some of those actively interested in a new standard procedure for shellfish was held at the Army Medical School in Washington, D. C., on April 18, 1935. A very free discussion of the problem of new standards took place. Summaries of the answers to the questionnaire were used as a basis for criticism and discussion. A copy of the report on this conference and of the questionnaire, together with the summary of the replies to the questionnaire, was immediately sent to interested persons for their further criticism.

APPROACH TO NEW PROCEDURE

The guiding policy in formulating a new procedure has been first to determine the attitude of those who have had extensive experience and particularly those who have given studious thought to the matter, secondly to review these attitudes critically and finally, with this background, to attempt to evolve a procedure.

---

* Progress Report of the Referee on Shellfish Standards for the Committee on Standard Methods for the Examination of Dairy and Food Products.

PRIMARY PURPOSE OF A PROCEDURE

It is obvious to all that the primary purpose of a standard procedure is to provide a method whereby the best possible knowledge may be had of the amount of fecal pollution in shellfish. The chief danger is typhoid fever. Lesser hazards are other enteric infections such as bacillary dysentery, paratyphoid fever, and cholera. It is also thought by some that there is a danger in transmitting other infectious diseases such as tuberculosis, syphilis, and skin infections, if people with these infections open shellfish. Physical and laboratory examinations for these diseases are, however, made routinely on employees in shellfish establishments, and it is not necessary to provide any special procedure for this purpose. The purpose, therefore, of this report, is to determine a procedure whereby the freedom of oysters and other shellfish from possible enteric organisms may be estimated.

It has not been considered necessary to publish the full report of the author in which the evidence both in favor of these and other minor changes, and that opposed to them was given. Since the part dealing with the proposed use of *Escherichia coli* rather than the colon group represents a more fundamental change than any other, and since the reasons for this change are of interest to many besides those interested in shellfish standards, this and a few other parts of the paper believed to be of general interest are given below.

The fact that the colon group has been found to be of so little value in estimating fecal pollution in oysters has made it mandatory that a more satisfactory index be found. The fact that *Escherichia coli* is the one member of the colon group which is generally accepted as an unquestionable and typical fecal type, and the fact that this organism has not been found to any extent in oysters, even those giving exceptionally high scores, unless such oysters were known to come from polluted areas, has naturally led many to believe it would be more satisfactory for this purpose. An impasse has been reached where it would seem that either some more suitable indicator of significant fecal pollution must be found, or the bacteriological examination of oysters must remain in a position of very questionable value, and be abandoned or discredited by many able workers. The use of scores based on the colon group as an indicator of pollution in oysters directly from their beds is already obsolete in Maryland and Canada. In this connection it is of interest and value to know that *Escherichia coli* was adopted by an international conference on a standard procedure for the examination of edible mollusks at Middleburg, Holland,[1] in September, 1932. Typical *Escherichia coli* is described as (1) a Gram-negative, nonsporing bacillus, (2) producing acid and gas from lactose, and (3) glucose, (4) producing indol, (5) giving a positive methyl red, (6) a negative Voges-Proskauer test, and (7) failing to grow in Koser's citrate medium. These are precisely the characters recommended by the writer [2] in 1928.

Realization of this situation has been the impetus which has resulted in a study for a practical method for the determination of *Escherichia coli* in Maryland. The fact that oysters, taken from sources of unquestionable purity as judged by sanitary surveys and bacteriological examination of the oyster waters, would frequently have excessively high scores during the warm summer and fall months together with the fact that the bacteria responsible for such scores were found to be almost exclusively *Aerobacter cloacae, Citrobacter sp., Aerobacter aerogenes*-like types and various intermediate colon group types to the exclusion of the

universally accepted fecal type, *Escherichia coli*[2, 3] indicates that the scores of oysters would be more significant if based on *Escherichia coli.* Not only is this true for shell oysters taken directly from their beds but it is a well established fact that in many instances the same type of colon flora is found in shucked oysters.

Since there is general agreement among bacteriologists that *Aerobacter cloacae* is one member of the colon group which is seldom found in human stools and is, therefore, generally accepted as not being a fecal type, and since this organism so often composes a large part of the colon group responsible for the type of high scores referred to,[2] there can be little objection to referring to the non-*Escherichia coli* members of the colon group in oysters as non-fecal types. It is obvious, therefore, that such non-fecal types find a natural habitat in oysters where a suitable food environment exists. Such forms are frequently the cause of excessively high scores in shucked oysters and undoubtedly are the cause for numerous complaints, investigations, and rejections where, as a matter of fact, they are probably without significance as indicating fecal pollution. They are found in large numbers in the dirt from unsanitary utensils, and easily increase in oysters if kept at comparatively warm temperatures. They may be present in large numbers to start with, and being able to tolerate a higher acidity than *Escherichia coli* they are, apparently, more characteristic of spoilage. This is the situation that has convinced many that *Escherichia coli* would be a more satisfactory index of fecal pollution in oysters.

In this connection it is of interest to review the attitude of those answering this question in the questionnaire and to know the attitude as expressed at the Washington conference. Of 24 persons answering the question, 14, or 57.3 per cent, favored the use of *Escherichia coli,* while 2 others, making 66.7 per cent, favored its use along with the colon group. Five, 21 per cent, favored the use of the colon group, while 3 others, a total of 33 per cent, considered the use of *Escherichia coli* impractical.

A very free discussion of this question took place at the conference and great interest in the problem was evident. In view of the acknowledged very limited value of the scores of oysters as now based on the colon group and the conviction that many members of this group are without significance from the standpoint of fecal pollution, the general opinion of the conference was in favor of using *Escherichia coli,* provided a satisfactory technical procedure could be developed.

In realization of the fact that scores based on the colon group are of no practical value, routine examinations for *Escherichia coli* (so-called fecal scores) rather than the colon group were instituted in Maryland in May, 1934. A great deal of work has been done since 1928 in the development of the Eijkman test[2] in the Maryland bacteriological laboratories because this seemed to offer the most practical approach to the problem of isolating *Escherichia coli.* A new Eijkman medium was developed and reported in 1933.[4] A report on the practical application of this test in the examination of oysters, crabmeat, and other substances was made in the JOURNAL of this Association in June, 1935.[5] A further report of the application of the test to the isolation of *Escherichia coli* from sewage appeared in the *Journal of Bacteriology.*[6]

Since the use of *Escherichia coli* seemed to be the key to the development of a new shellfish procedure, and since considerable work had been done in Maryland for some months, the services of Dr. Milward Bayliss were

secured for 2 months from funds provided by the Committee on Research and Standards to help compile the Maryland data. It was planned to include other data but these could not be secured.

The Maryland data were compiled to demonstrate what correlation, if any, there might be between pollution as estimated from sanitary survey information and pollution as indicated by *Escherichia coli* and by the colon group. A short report of these observations with charts has been submitted for publication in the *Journal* of the Association. Data were compiled for 4 rivers in Maryland, and a single table for all *Escherichia coli* data available has been prepared. In brief, these data indicate a close correlation between the estimated degree of fecal pollution as judged by sanitary surveys and as indicated by *Escherichia coli* densities in oysters, while there is little or no such correlation on the basis of the colon group. For the oyster producing waters there is a much closer correlation between observed pollution and the colon group, but even here there appears to be a much better one on the basis of *Escherichia coli.*

The Maryland data are too limited to warrant dogmatic conclusions but they justify further study.

STANDARD PROCEDURE FOR EXAMINING SHELLFISH WATERS AS WELL AS SHELLFISH

Practically all of those replying to the question, " Should a standard procedure for shellfish include one for shellfish waters? " indicated that a procedure for examination of the waters should be a part of standard methods for the examination of shellfish. Two only, felt that since the Association already has standards for the examination of water this should not be included. The principal reasons why a separate procedure is needed may be listed as follows:

1. The present standard method has been developed for drinking water; it has not been found satisfactory for estimating the quality of water suitable for growing shellfish.
2. Most of those concerned with the shellfish problem believe that *Escherichia coli* rather than the colon group would be a more suitable index of the type of pollution with which they are concerned.
3. There is general agreement that the same bacterial index of pollution should be used both for shellfish and shellfish waters.

The sentiment of the conference was in accord with the above summary of the attitude of those answering the questionnaire. The Maryland data on the relative value of *Escherichia coli* and the colon group support these points.

RECOMMENDED LIMITS FOR POLLUTION

The opinions of those with experience in shellfish control work differ sharply on the question of whether limits should be defined for pollution.

About two-thirds (15) of those an-answering this question favored the adoption of bacterial limits. A number indicated that such bacterial limits, however, should be based on *Escherichia coli.* Six were opposed to the established bacterial limits.

The opinion voiced at the conference was in opposition to stringent definition of standards. It approved, however, the inclusion of certain carefully phrased recommendations made on limits for pollution arrived at by those responsible for official control work.

In so far as procedure and limits of pollution are so intimately a part of each other, in so far as those who are best qualified to arrive at a desirable standard procedure are probably also best qualified to judge the significance of the practical application of this pro-

cedure, and in so far as a number of those concerned with the problem of evaluating bacterial results and determining pollution desire advice in this matter, the adoption of some sort of guide would seem to be useful. Such a recommendation should, however, follow the application of the new procedure in a relatively large series of examinations made on shellfish and shellfish waters of various degrees of pollution.

USE OF WHOLE OYSTER RATHER THAN SHELL LIQUOR

The question of whether an examination of shell liquor gives a proper idea of pollution in oysters and other mollusks has received considerable thought in this country, in England, and elsewhere. In Japan,[7] the American procedure has been used and will be adopted with certain modifications, chiefly the use of the whole oyster rather than shell liquor. In Germany,[8] there is no standard procedure and examinations by one of two private companies are confined to direct microscopic examinations of stained tissue for spoilage. In England, there are likewise no standard procedures comparable to those of the United States. The Bacteriological Standards of the Worshipful Company of Fishmongers [9] are, however, almost tantamount to such standards. Their procedures have been reviewed and approved by representatives from the Royal Society, and the Oyster Merchants' and Planters' Association, as well as from the Ministries of Health and of Agriculture and Fisheries in 1924. The procedures represent the long experience and thought of Sir Alexander Houston, Dr. Klein, Professor Eyre of the Fishmongers Association, Sir Frederick Andrewes of the Royal Society, and Professor R. Tanner Hewlett, representative of the Oyster Merchants' and Planters' Association. A most important point in the procedure is the use of the whole oyster. This procedure has, however, recently been superseded in reality by the recommendations of the Middleburg conference.

It is pertinent that under the auspices of the Conseil International pour Exploration de la Mer [1] at a conference held at Middleburg, Holland, in September, 1932, a standard method for the bacteriological examination of edible mollusks was considered. This conference was represented by delegates from Belgium, England, France, Germany, Holland, Irish Free State, and Portugal who were for the most part experts in this type of work. The procedure adopted by this conference is excellent in most regards and should receive careful consideration in the formulation of our own revised methods. It is noteworthy in connection with the point under discussion that the procedure adopted calls for discarding the shell liquor and using only the minced bodies of the mollusks. While a question may be raised on the validity of discarding the shell liquor, all evidence indicates the soundness of using the minced body of the oyster.

In the United States, the relative merits of using the whole oyster rather than the shell liquor for examination have been investigated particularly by Dowd and Glancy [10] of the Pease Laboratories, by Tarbett [11] of the U. S. Public Health Service, and, more recently, by the author and a member of his staff.[12] None of the results of these studies have been published, but the writer has had an opportunity to review the work of Dowd and Glancy and is familiar with Tarbett's conclusion that the whole oyster should be used. The studies made in Maryland confirm Tarbett's conclusion. The answers to this question in the questionnaire were not very conclusive, an equal number favoring the use of the whole oyster and the continued use of the shell liquor. The opinion of the

conference was strongly in favor of the use of the whole oyster.

USE OF MOST PROBABLE NUMBER VS. THE SCORE FOR EXPRESSION OF RESULTS

The score method of expressing the number of colon group bacteria in oysters has been subject to considerable criticism. While there is now general familiarity with oyster scores among those concerned with the sanitary control of shellfish, and there might consequently be some objection to changing a system so well established, yet this argument is not entirely valid. In the first place, of 22 persons expressing their attitude on this point in the questionnaire, only 9, or 41 per cent, favored retention of the score system against 13, or 59 per cent, who favored the use of most probable numbers. Those attending the conference were also in favor of expressing results as most probable numbers. A point of practical consideration is the association of certain scores, particularly a score of 50, as indicative of significant pollution. While such associations have been discredited, yet the association will remain in many minds for a long time. The transition to a new basis for measuring pollution as *Escherichia coli* will of course necessitate new standards. It is believed that this transition can be effected much better if results are expressed in most probable numbers. The score system is already obsolete in several places, notably Canada and Maryland where results are expressed as most probable numbers, and the score system is used in Maryland only for interstate purposes. It is proposed, therefore, that results for both shellfish and shellfish waters be expressed in terms of most probable numbers.

SUMMARY

On the basis of a questionnaire, conference, and consideration of studies made both in the United States and certain foreign countries, the following principal changes in the present standard procedure for the examination of shellfish are proposed.

1. A new procedure should include at least, such edible mollusks as oysters, clams, and mussels.
2. *Escherichia coli* rather than the colon group should be the index of pollution for both shellfish and shellfish waters.
3. A new procedure should include methods for the examination of shellfish waters as well as shellfish.
4. The whole oyster rather than just the shell liquor should be examined.
5. *Escherichia coli* results should be expressed as most probable numbers rather than as a score.
6. Certain recommendations should be made in regard to amount of pollution which should ordinarily be tolerated.

A procedure incorporating these principles has been drawn up for trial during the ensuing year, during which time it is hoped its value for testing oysters, clams, and mussels may be determined and such changes made in it as will best adapt it to the requirements of practical application.

Procedures for the Detection of Brucella in Milk*

EXAMINATION OF MILK (COW, GOAT AND SHEEP) FOR BRUCELLA AGGLUTININS

Collection and preparation of milk samples—Milk samples are collected, preferably from individual quarters of the udder, in clean test tubes or vials. The strippings should never be used. The tubes should be filled to only one-half their volume. Let the samples stand from 6 to 8 hours to permit the cream to separate. Remove as much of the cream as possible with a pipette. Add rennet (1 per cent solution), allowing 2 drops for each 5 c.c. of milk, to each tube of milk, and mix thoroughly. The tubes may be placed either in an incubator at 37° C. or in warm water at the same temperature. If the tubes are placed in a slanting position, the curd will settle to one side, and the clear milk serum with which the test is to be made will separate in about 2 hours. In order to obtain a serum free from particles of casein, the samples should be placed in an icebox or cold place for from 6 to 8 hours before testing. Sour and decomposed milk should not be used, as the results are not reliable. Neither should milk be used in which the curd has become partly digested as this interferes with the test. Colostrum is unsatisfactory because of the difficulty of separating the serum and the possible occurrence of nonspecific agglutinins.

The Agglutination test—One may choose either of two methods, namely the test tube or rapid agglutination test.

Test tube method—A smooth strain of *Brucella abortus* is grown on liver agar slants for 48 to 72 hours at 37° C. The growth is removed and suspended in physiological salt solution containing 0.5 per cent phenol. The final turbidity of the suspension should measure 7 cm. by the Gates wire loop method. Place 2 c.c. of the antigen into a series of 5 agglutination tubes. To the first tube add 0.08 c.c. of milk serum, the second 0.04 c.c., the third 0.02 c.c., the fourth 0.01 c.c., and to the fifth 0.005 c.c. These amounts of milk serum added to 2 c.c. of antigen will give approximately, dilutions of 1–25, 1–50, 1–100, 1–200, and 1–400. No further dilutions are necessary in making routine examination of milk for *Brucella* agglutinins.

Serum and antigen are mixed thoroughly in the tubes and incubated for 48 hours in a 37° C. room.

The following system may be used in recording changes in the stability of the antigen: + = complete sedimentation; P = incomplete sedimentation; — = no sedimentation. The presence of infection in the udder is indicated by complete agglutination in a 1–50 dilution or above of serum.

Rapid agglutination test [1]—The rapid agglutination test offers a simple and accurate method of detecting *Brucella* agglutinins in milk from any species of animal infected with any one of the three species of Brucella.

Materials needed — (1) darkfield illumination box and glass plate ruled into squares; (2) 0.2 c.c. pipettes graduated in 0.01 c.c.; (3) clean toothpicks for mixing milk serum and anti-

* Supplementary report of the Associate Referee on Methods of Examination of Milk for Evidence of Brucella Infection, for the Committee on Standard Methods for the Examination of Dairy and Food Products.

gen; (4) properly standardized antigen and standardized dropper pipette.

Technic—In beginning the test, arrange the serum samples in a row parallel with the darkfield illumination box. The glass plate, with the etched squares upward, is placed over the opening of the box and the identification number of the serum sample marked with a wax pencil on either the top or bottom of the row of squares used.

With a clean 0.2 c.c. pipette, draw up serum from the first milk sample to the zero mark on the pipette. Beginning in the bottom left hand square of the plate, place the following amounts of serum in the succeeding squares toward the top: 1st square, 0.08 c.c.; 2nd square, 0.04 c.c.; 3rd square, 0.02 c.c.; 4th square, 0.01 c.c.; 5th square, 0.005 c.c.

This manner of placing the serum brings the smallest amount farthest from the heat of the electric bulb in the box, reducing the rapidity of drying of the smallest amounts of serum. The procedure is continued, using the next set of vertical squares and a separate pipette for each sample. The best results are obtained by testing only 4 or 5 samples at a time as otherwise the small amounts of serum dry out too much before the test is completed.

If the pipette has been placed deep in the serum, there will be some serum which will collect on the outside at the tip. For accuracy, this should be removed by touching the tip of the pipette against the lip of the vial.

After thoroughly shaking the bottle of antigen, remove a dropper full of the antigen. Holding the dropper in a vertical position, add one drop to each amount of serum on the plate. Care should be taken to hold the dropper in a vertical position since holding it at another angle will make a considerable difference in the amount of antigen delivered. Always replace the dropper directly in the vial of antigen.

Then with a clean toothpick mix the serum and antigen, using a new toothpick for each sample. Always start at the top of the plate in the square containing the smallest amount (0.005 c.c.) of serum and continue downward to the largest amount. Spread the mixture over about three-fourths the area of the square without coming in contact with the etched dividing lines.

Immediately after the samples have been mixed, remove the plate from the box and tilt slightly backward and forward slowly for about 5 minutes. Place the plate on the box, turn on the light, and record the results.

The reactions stand out very clearly. It is not difficult to distinguish between complete clumping of the antigen and different degrees of incomplete clumping. A negative serum causes no flocculation of the antigen. There are often encountered, however, sera which produce a trace of flocculation in the 0.08 c.c. amount.

Immediately after using, the pipettes should be rinsed several times with fresh water until thoroughly clean. Then boil in distilled water and drain all the water out before using again. The glass plate may be cleaned with cleaning powder and brush, after which it is rinsed with distilled water and dried. By having several clean plates available, one can proceed with the testing of additional samples without delay. Absolute cleanliness of glassware is essential.

Interpretation of the test—Rapid antigen has been standardized for use with undiluted serum in the following amounts: 0.08 c.c., 0.04 c.c., 0.02 c.c., 0.01 c.c., and 0.005 c.c.

In the test tube method, when these amounts of serum are added to 2 c.c. of antigen (turbidity 7 cm. by Gates apparatus), the following respective approximate dilutions are obtained:

1–25, 1–50, 1–100, 1–200, and 1–500.

The antigen has been standardized so that the titer of the agglutinins in a given serum will be parallel in the two methods. Therefore, in the rapid test, complete agglutination with the various amounts of serum represents the following titers: 0.08 c.c., 1–25; 0.04 c.c., 1–50; 0.02 c.c., 1–100; 0.01 c.c., 1–200; 0.005 c.c., 1–400.

If one desires to employ quantities of serum different from those just mentioned it will be necessary to standardize the antigen for the amounts in question. It is important to acquire an accurate knowledge of reading the test. If possible, a visit should be made to a laboratory conducting the test to obtain assistance in reading and interpreting the different degrees of agglutination.

The interpretation of the different degrees of agglutination in terms of infection is still a debatable question. One should conform to the interpretation placed on the test by the regulatory or sanitary authorities of the state in which the test is conducted.

The presence of infection in the udder is indicated by complete flocculence of the antigen with 0.04 c.c. of milk serum. In the case of a composite milk sample, infection is indicated when flocculence occurs with 0.08 c.c. of serum.

Differentiation of the Species of Brucella—It is important that one be thoroughly familiar with the peculiar growth characteristics of the Brucella group and the methods that have been successfully used in their differentiation, before an attempt is made to identify the species of a newly isolated strain. It is advisable for those laboratories which isolate cultures at wide intervals to forward new cultures for their identification to laboratory workers who have had considerable experience with the Brucella group.

There are five methods that have been used successfully with certain limitations, for the identification of the species of Brucella. The agglutinin-absorption method was used first by Feusier and Meyer [9] for this purpose. It was studied more exhaustively by Evans [10] and by Wilson and Miles.[11] It is a valuable method for distinguishing *Brucella abortus* from *Br. melitensis* if the technic employed by Wilson and Miles [11] is followed, otherwise it will fail to distinguish one from the other in certain instances. The agglutinin-absorption method is not a reliable one for distinguishing rough strains of melitensis from rough strains of abortus nor will it separate *Br. suis* from *Br. abortus*.

If one is desirous of using the agglutinin-absorption method in determining whether a strain belongs to the abortus or melitensis group, it is recommended that the technic of Wilson and Miles [11] be followed.

The glucose utilization method, first applied and recommended by McAlpine and Slanetz [12] for identifying the species of Brucella, has not found general acceptance by many other workers.

The difference in the nitrate and nitrite reducing ability of the species of Brucella has been made use of by Zobell and Meyer [13] as a means of distinguishing one from the other. Their results obtained by this method have been confirmed by the writer. The method should be employed, wherever possible, in determining the species of a newly isolated culture.

The difference in the hydrogen sulphide metabolism of the three species of Brucella has been made use of by the writer [1] in distinguishing one species from the other regardless of their source or whether the culture is smooth or rough. There is one group of strains the writer and others have studied which cannot easily be identified by the H_2S metabolism method.

They are the Danish strains of *Br. suis*. These strains do not produce H_2S to the same degree that other strains of *Br. suis* produce.

A method [1] which makes use of the difference in growth behavior of the species of Brucella toward certain aniline dyes in a solid medium has been generally accepted as the most satisfactory for identifying the species to which a given culture belongs.

The following technic should be followed in using the dye plate method for identifying the species of Brucella: The medium used is prepared according to the formula given at the end of this section. The pH is adjusted to 6.6. The adjustment should be made just before the dyes are added, as liver infusion medium does not always remain at the pH to which it was previously adjusted if it is heated afterward. This point should be observed closely if successful differentiation of the species is to be obtained. A medium of higher or lower pH gives such confusing results that perfect differentiation is impossible.

The dyes which have been found to give consistent results in the differentiation of the three species are thionin and basic fuchsin. They are certified dyes, made by the National Aniline and Chemical Company.

The dyes are prepared in a 1 per cent stock solution or suspension in sterile distilled water. They are not readily soluble in water in this concentration. The stock solutions appear to keep indefinitely. The final dilution which should obtain for thionin is 1:50,000 and for basic fuchsin 1:25,000. These dilutions are based on the actual amount of the original dye in the medium.

The dye suspensions should be heated in flowing steam for 20 minutes, shaken well and, while still hot, added to the melted medium before it has time to cool. This procedure results in a more uniform mixture of the dye suspension and a more uniform distribution of the dyes in the medium. The medium and dyes are thoroughly mixed and immediately poured into Petri plates. The plates are placed in a 37° C. incubator until the water of condensation disappears.

The plates may be divided into three or more sections to accommodate the growth of several strains of the organism. The seeding of the plates is accomplished with a loop of a heavy suspension of a 48 to 72 hour agar slant growth. The suspension may be obtained by working up a portion of the growth in the water of condensation at the butt of the slant or by adding a small amount of sterile broth or sterile saline solution to the slant. It may be stated here that the dyes do not kill the organism, but merely inhibit its reproductive function; so if masses of the culture are streaked over the surface of the plates, slight growth is very apt to occur at those points where the seeded mass has not been evenly distributed.

The seeded plates are incubated aerobically at 37° C. for 72 hours, or in 10 per cent CO_2 when newly isolated bovine strains are used. At the end of the period of incubation one will find that strains of the abortus species have grown only on the medium containing basic fuchsin; those of the suis species have grown only on the medium containing thionin; and those of the melitensis species have grown on each of the media. The growth of the last species, however, is as a rule never as luxuriant as that of the other two species.

PREPARATION OF LIVER AGAR MEDIUM [1]

The medium is prepared as follows: Fresh beef liver, free from fat, is ground in a meat chopper to a plastic mass. One pound of the liver and 500 c.c. of tap water are placed in a con-

tainer and mixed well. The container is covered and placed in flowing steam for 20 minutes. Remove the lid and stir with a glass rod in order to mix thoroughly so that all parts are reached by the heat. The heating is continued in flowing steam for 1½ hours. Remove and filter through a wire screen. The infusion thus prepared is made into a solid medium or infusion broth.

To prepare one liter of liver infusion agar, measure out the following ingredients:

Washed agar	20 gm.
Tap water	500 c.c.
Liver infusion	500 c.c.
Peptone (Bacto)	10 gm.
Sodium chloride C.P......	5 gm.

Place all ingredients in a suitable container, cover and place in flowing steam for 1 hour. Remove and cool to 60° C. Adjust the pH at this time to 7. Place in flowing steam again for ½ hour. Decant and place in sterile flasks or tubes and sterilize at 15 lb. pressure for 30 minutes. The reaction of the medium during the process of sterilizing will usually drop to or near pH of 6.6. In the writer's experience the organisms grow best at or near pH of 6.6. The final medium prepared according to the foregoing method will not be clear, but this will not interfere with its use as a medium. The final product may be freed from sediment and suspended particles if it is passed through a Sharples centrifuge before sterilization.

Liver broth for blood culture or other use may be prepared in the same way.

Examination of Water and Sewage*

THE committee this year offers definite recommendations for changes for the Eighth Edition of *Standard Methods for the Examination of Water and Sewage.* While the definite proposals will be recommended for action in a later business meeting of the Laboratory Section, it seems desirable to present before this meeting some discussion of these specific changes, together with more general considerations, which, although of an editorial character, should be brought to the attention of those interested in water and sewage analysis. Most of the proposed changes were anticipated in the report presented in 1934.

A rearrangement of material in the various Parts of the book is made necessary by the inclusion of more complete procedures for sewage analysis and for boiler water examination, in order to place the methods in the sections to which they are most applicable and to avoid repetition.

Part I will contain the procedures most frequently used in sanitary chemical analysis.

Part II will include methods more often used in mineral analysis, together with the new section on boiler water analysis, and the present section containing rapid methods which are used primarily in railroad laboratories. It is of course impossible to avoid some arbitrary decisions in assigning the procedures on this basis.

The methods for dissolved oxygen and oxygen consumed have been transferred to Part III which deals with sewages and sewage effluents and has been prepared by a committee from the Sewage Works Association. Part IV contains methods for the analysis of sludge, etc.

Parts V and VI deal with microscopic analysis, and Part VII includes the bacteriological methods. Certain procedures now contain rather rigid specifications for laboratory apparatus. It has seemed convenient to gather this material in one section.

The more important changes in methods will be discussed.

The determination of odor has been completely revised and now includes the so-called "threshold" method, embodying the ideas of Spalding as recommended by Fair and his associates, and an optional air dilution test.

More discussion has been aroused by the present procedure for estimation of chlorine than by any other of the chemical analyses. This has led to a complete revision of the procedure and its modification to allow for the numerous interfering substances. In the presence of relatively large amounts of nitrite nitrogen and manganic compounds the ortho-tolidine method is unusable, so that an iodine procedure has been added.

In the western part of the country it is sometimes necessary to determine the borate content of a water. The method now in Appendix II has been used in extensive studies by the Los Angeles Water Department and found sufficiently satisfactory to warrant the recommendation that it be included as a standard procedure. Two other determinations should also be similarly transferred: The nephelometric method for zinc, and the DeBoer method for fluorides by the use of the zirconium-alizarin reagent.

* Report of the Standard Methods Committee.

For some time the various committees in charge of revising Standard Methods have hoped to include more accurate procedures applicable to boiler water analysis. This section has been prepared under the direction of S. T. Powell and includes the methods recommended by the American Society for Testing Materials.

The procedure for microscopic methods has been revised and a table has been placed in the Appendix to give suggestions for interpretation of results.

In the paper presented by Mr. Ruchhoft, the basis for changes in bacteriological methods has been discussed. The large amount of laboratory data involved has been obtained in a coöperative investigation under Mr. Ruchhoft's direction, and the committee is highly appreciative of the interest and coöperation of the more than 20 laboratories involved. Various media were studied on the basis of their growth promoting properties for the coli-aerogenes group and their inhibitive action toward anaerobes. Much of the latter work was done by Dr. R. S. Spray. From the data obtained, certain media were selected for use in a confirmatory test for the coli-aerogenes group. None of the special media studied were considered satisfactory to supplant lactose broth for primary inoculation with portions of water samples but are satisfactory for confirmation. It is hoped that this new procedure will materially shorten the present standard method and will give results equally satisfactory from a sanitary standpoint.

The entire section on bacteriological methods has been carefully revised, and a new schematic outline prepared. The most important changes in these methods are those dealing with the detection of organisms of the coli-aerogenes group. It is proposed to recognize 3 tests—presumptive, confirmed, and completed. No change is recommended in the presumptive test except that tubes showing gas after 48 hours should be confirmed rather than completed. The confirmed test may be done either by the use of Endo or eosin-methylene blue plates, as at present, or by the use of one of 4 confirmatory media:

Brilliant Green Bile
Crystal Violet Lactose Broth
Fuchsin Lactose Broth, or
Formate Ricinoleate Broth

The formation of gas in any one of these media following the formation of gas in a lactose broth tube will constitute the confirmed test. No change has been made in the completed test except that completion may be made from a confirmatory medium as well as from Endo or eosin-methylene blue plate. It is desirable, but not required, in selecting the confirmatory medium that the medium be studied in relation to the particular water supply under examination, and that the one be chosen which gives the most satisfactory correlation with the completed test.

One addition has been made to the committee since last year. Dr. W. L. Mallmann has been added as a member in charge of methods for swimming pool examination. In general, these methods would follow those of sanitary water analysis, but it is well known that certain precautions must be taken in collecting samples from chlorinated pools. Inasmuch as Dr. Mallmann is the Laboratory Section representative on a committee of the Public Health Engineering Section, it is not possible to include his report in the main body of the text of *Standard Methods* until a report is approved by the committee. However, his suggestions will be included as an Appendix to *Standard Methods*.

Below are the definite recommendations of the committee:

Proposed Recommendations for Presentation to the Laboratory Section by the Coördinating Committee and Relating to the Eighth Edition of Standard Methods for the Examination of Water and Sewage

As in the past, these recommendations include only proposed changes which are fundamental in character, *i.e.*, new methods which the committee recommends for inclusion in the Eighth Edition and fundamental changes in present methods. Since the new manuscript must be approved, both by the Coördinating Committee and the Committee on Research and Standards, it is believed that sufficient safeguards exist over proposed changes of an editorial character.

The following changes and additions are recommended:

1. The addition of a section dealing with laboratory apparatus, this section being a compilation of specifications already included in the text under various methods of analysis.
2. The use of milliequivalents per liter in figuring chemical constituents in addition to parts per million.
3. The so-called "threshold" method for detecting odors in water, essentially that proposed by Fair. The air dilution method is an optional procedure. This involves the use of more descriptive terms than at present employed, together with the use of code letters.
4. A revision of the test for chlorine, involving a modification of the time allowed for color development. This will be not less than 5 minutes and not more than 15 minutes, with the provision that a less time may be used under special circumstances. Where interfering substances are present, procedures will be given in the appendix.
5. The carbamate method for the examination of copper in place of the electrolytic procedure.
6. The deletion of the present method for tin.
7. The method for estimating zinc now given in the Appendix (nephelometric ferrocyanide method).
8. The method for boron now described in the Appendix (electrometric).
9. The DeBoer Method for estimating fluoride (colorimetric with zirconium-alizarin reagent).
10. Perchloric acid method for potassium.
11. The method for determination of iodide now given in the Appendix (colorimetric with nitrosyl-sulphuric acid reagent).
12. The elimination of the method for oxygen consumed in Part I of the book and the transfer of this procedure to Part III dealing with sewage analysis, leaving an appropriate cross-reference.
13. Transfer of the determination for dissolved oxygen from the section dealing with water analysis to the section dealing with sewage analysis with appropriate cross-reference.
14. A determination for total solids in brines. Drying at 750° C.
15. Permission to use other than specified indicators in alkalinity.
16. Addition of a colorimetric method for silica (ammonium molybdate).
17. Phosphate method now in Appendix (precipitation as phosphormolybdate and as magnesium ammonium phosphate with ignition—Scott method).
18. A section entitled, "Analysis of Stationary Boiler Water Supplies"; this section to include the following new determinations:

Strontium chloride method for hydroxide.

Barium chloride and carbon dioxide evolution methods for carbonate.

Benzidine and tetrahydroxyquinone methods for sulphate.

Colorimetric method for phosphates (aminonaphtholsulfonic acid).

Dissolved oxygen—a modification of the Winkler procedure to detect small amounts of oxygen.

Sulphite (iodine titration).

Cross-references have been used for methods in other sections of the book.

19. The adoption of the methods for sewage analysis, including sewage sludge and muds, as proposed by a committee of the Federation of Sewage Works Associations and published in the *Sewage Works Journal* for May, 1935. These methods will be edited only sufficiently to conform to the rest of the text. They do not include any essentially new items—except that for chlorine demand—but represent, rather, modifications of present procedures. Where possible, references are made to other portions of the text rather than repeating complete procedures elsewhere described.

20. The inclusion in the section on sewage analysis of the complete procedures for the determinations for oxygen consumed and dissolved oxygen.

21. In the microscopic method, complete description of the use of the centrifuge for concentration is included. It is proposed to include in the Appendix of the volume a table with suggestions for the interpretation of results.

22. Dilution water for use in the bacteriological procedures may be either tap water or one of the dilution waters recommended in the test for biochemical oxygen demand.

23. In the bacteriological methods it is proposed to set up 3 tests for the detection of the coli-aerogenes group:

Presumptive Test
Confirmed Test
Completed Test

The presumptive and completed tests are essentially those in the present edition. In the confirmed test, it is proposed to allow the use of Endo or eosin-methylene blue agar plates or to confirm in one of four specified liquid media—confirmation to be complete when gas appears within 48 hours in the confirmatory medium inoculated from tubes showing gas as a result of primary planting in lactose broth. These media are:

Brilliant Green Bile
Crystal Violet Lactose Broth
Fuchsin Lactose Broth
Formate Ricinoleate Broth

24. Completed tests may be made either from lactose broth tubes showing gas or from tubes of a confirmatory medium showing gas.

25. Parallel planting in lactose broth and brilliant green bile for control in water purification plants be removed from the text and placed in an Appendix.

26. The formula for the preparation of Endo media has been revised in accordance with the work of Conn in coöperation with the members of the committee. The essential feature of this is a more definite statement in regard to the stock solution of fuchsin. The proposed strength is a 3 per cent solution. The present optional formula for Endo medium will be placed on a par with the first formula.

27. The method for calculating the coli-aerogenes group density, known as the Most Probable Number. The present method of calculating this index is retained as an alternative procedure for the use of single samples of water and will be known as the Indicated Number.

While the above constitute the definite fundamental changes recommended by the committee, it is desirable that the section be informed concerning certain proposed rearrangements of an editorial character. Some of these rearrangements have been mentioned above because of fundamental importance. Others include the division of Part I into two parts, the first to contain methods essential to or used in the sanitary examination of water, and the second part to contain the procedures dealing with mineral analyses. While it is recognized that such a division must be somewhat arbitrary because certain determinations might be included in either section, it is believed that this division will facilitate the use of the book. A new system of numbering the paragraphs will be used with the hope that cross-references will be less complicated than at present. This consists of a modification of a decimal numbering system. Certain of the procedures have been rewritten because of criticisms received from numerous sources. For example, the method for the determination of chlorine has been entirely revamped, as have the sections on turbidity, hardness, microscopic methods, and bacteriological procedures. In the latter, a new schematic arrangement to include the methods for the detection of the coli-aerogenes group has been devised and this will replace two of the present

sections which were found to be more or less cumbersome. The "outline of the daily routine" has been deleted. In connection with the newly recommended confirmatory liquid media, it has, of course, been necessary to include the method of preparation of these media. The present statement concerning variations in media when large samples of water are used for examination, has been clarified.

Diagnostic Procedures and Reagents

THE Section on Diagnostic Methods and Reagents of the Standard Methods Committee of the Laboratory Section has now been working for 2 years. Only one new referee, Dr. Henry P. Welch, referee for typhus fever, has been appointed since the last report. The referees and the subjects they are investigating are named in the *Year Book* for 1934–1935. In that report there also appear papers by several of the referees which are preliminary reports on the formulation of what has been called standard laboratory methods for the diagnosis of certain communicable diseases. In these reports it is clear that neither the committee nor any referee has approached the problem with the idea that methods will be devised which are final and unchangeable. It is well understood by the committee that anything which we report can be looked upon only as recommended methods and what we consider to be the best technic in view of our present knowledge to demonstrate characteristic biological features of certain microorganisms. Often during discussions of the desirability of the description of such methods objection is raised to the use of the phrase: "Standard Methods." The objection is always based upon the idea that there is implied by this phrase methods which are fixed and unchangeable, and that the Association is forever committed to them as the final opinion upon a completed subject.

Such controversies seem to show a complete failure to comprehend the purpose of recommending methods of procedure. It is, of course, apparent to all that the environment which we create for microörganisms determines what their reaction will be. Therefore any new knowledge concerning the influence of environment on their behavior may at once modify the technic used for the demonstration of their biological reactions. With an understanding of the shortcomings of our knowledge concerning the influence of environment upon the behavior of pathogenic microörganisms, and the behavior of these organisms to different environmental conditions, it is readily conceded that a final word on the methods to be employed in their study cannot now be said. But, on the other hand, the very uncertainty of our knowledge upon these questions makes more certain the importance of uniform methods of study. It needs no argument to show that if one laboratory attempts the isolation of *B. typhosus* from stools preserved in a special preservative, no comparison with the results of another laboratory which does not use such a preservative is possible. It is not alone for the purpose of comparison, however, that uniformity of method is desirable. Since the environment created by one laboratory is often so different from that of another, it is quite likely that one method gives better results than another or in certain instances a method may be entirely unsuited to the purpose for which it is used. A Standard Method, or recommended method, would give a uniformity growing out of a wide experience of many laboratories and out of the experience of large laboratories where time and money have made possible special investigation. Such methods, while not representing the ultimate of perfect knowledge, certainly do offer

an opportunity for the temporary or tentative standardization of methods.

In a discussion of the committee's conception of its task, there is another phase of laboratory work which should be mentioned, *i.e.*, the interpretation of laboratory results in terms of medical diagnosis. This phase of the work is influenced by so many factors which are not subject to methodology that no standard significance can be arbitrarily applied to any given laboratory results. Some of the factors which influence interpretations are the method by which the specimen is collected and how it is preserved, but at the juncture where the results of laboratory and clinical studies are put together is the point where standardization ends and where failure so often occurs. Failure results sometimes because the pathologist has not been supplied with sufficient clinical information upon which to base an interpretation of his finding. A contributing cause to such failure is due often to erroneous conceptions concerning the significance of laboratory findings. By some they are considered to be mathematically exact. No one knows better than the trained laboratory worker that such is not the case. There is no single laboratory determination which can be removed from the clinical environment which it was devised to elucidate, and its clinical significance evaluated. Thus the finding of morphological *B. diphtheriae* in a throat culture does not diagnose clinical diphtheria nor does a positive agglutination test diagnose typhoid fever, undulant fever, or other diseases, etc.

With all of these limitations in mind the Committee on Diagnostic Procedures and Reagents began its work of investigating the possibility of formulating methods which could more or less standardize certain phases of laboratory procedure. The first year was spent in selecting and appointing referees and in gathering data through questionnaires and by other means from laboratories throughout this country. The reports of these studies, those that have been completed, will be found in the *Year Book* and papers published in the *Journal* during 1935. The last year has been spent by the referees in the formulation of completed manuscripts describing methods of procedure for the recognition of infections with the various pathogenic microörganisms.

Because manuscripts from all of the referees have not been completed, and because those which are completed and ready for publication will undoubtedly be revised from time to time as information accumulates, it is recommended that the manuscripts which we now have be published in a loose leaf volume, and made available at a reasonable cost to laboratories wishing to use them. We now have 11 completed manuscripts, and there is another almost completed. The volume will therefore contain a description of methods used in the recognition of the following conditions and microörganisms.

1. Studies on the Toxicity of Brilliant Green for Certain Bacteria
2. Serological Tests for the Diagnosis of Syphilis
3. Serological, Bacteriological, and Other Biological Procedures in the Diagnosis of Undulant Fever
4. Recognition and Significance of Hemolytic Streptococci in Infectious Diseases
5. Serological and Bacteriological Procedures in the Diagnosis of Enteric Fevers
6. Whooping Cough and *B. pertussis*
7. Laboratory Diagnostic Procedures in the Recognition of Various Food Poisonings
8. Meningitis and Meningococcus
9. Gonorrhea and the Gonococcus
10. Amebiasis and *Ameba Histolytica*
11. Tuberculosis and the Tubercle Bacillus

Manuscripts which have been previously published in the *Year Book* but have been revised and manuscripts which have not been previously published are submitted with this report.

W. D. STOVALL, *Chairman*

Tentative Methods for the Diagnosis of Amebiasis and Amebic Dysentery*

I. Definition

"*Amebiasis* is the state of being infected with amebae. In practice it refers to *E. histolytica*." Dobell.

"*Amebiasis* is the invasion of the tissues of man by *E. histolytica*. The invasion is primarily through the mucous membrane of the large bowel—much more rarely through the mucous membrane of the ileum.

"*Amebic Dysentery* is a bloody mucoid diarrhea caused by *E. histolytica* and occurring as one of the manifestations of amebiasis." Craig.

II. Symptomatology

The symptoms vary from slight digestive disturbances to the most severe symptoms of amebic dysentery or amebic abscesses of the liver or other organs. In some individuals the symptoms are mild with few stools a day, while in others the symptoms are very severe—there is a sudden onset, with headache, severe colicky pain in the abdomen, malaise, tired, anxious, and drawn expression, tongue dry and furred, tenesmus and desire to defecate. There may be 6–30 bloody mucoid stools a day; emaciation, prostration and death from cardiac failure and exhaustion.

III. Etiology (*Endameba histolytica*)

Among the various amebae in man are:

* Report of the Referee on Amebiasis for the Standard Methods Committee on Diagnostic Procedures and Reagents.

Genus I. *Endameba* (Leidy, 1879)
Species in man—
E. histolytica, Schaudinn, 1903
E. coli, Grassi, 1879
E. gingivalis, Gros, 1849

Genus II. *Endolimax* (Kuenen and Schwellengrebel)
Species in man—
Endolimax nana, Wenyon and O'Connor, 1917

Genus III. *Iodameba* (Dobell, 1919)
Species in man—
Iodameba bütschlii

Genus IV. *Dientameba* (Jepps and Dobell, 1918)
Species in man—
Dientameba fragilis

IV. DIFFERENTIAL CHARACTERISTICS OF THE INTESTINAL AMEBAE OF MAN

The main criterion upon which the differences are based is largely the nuclear structure which involves the thickness of the nuclear membrane, size, type, and position of the karyosome, linin network (delicately stained fibrils in spaces between the karyosome and the nuclear wall), and chromatin granules. In addition to the nuclear structure, various other features are important—the number and type of nuclei, the type of chromatoid bodies, and the glycogen.

B. *E. Histolytica*

E. histolytica is divided into different races according to the size of cysts produced (Plates I and II).

Trophozoite—15–80 micron.

E. histolytica which produce small variety cysts are usually smaller and not quite as rapidly motile as those producing large variety cysts. In the cases which we have had we have never been able to find red blood cells in the trophozoites which gave rise to small variety cysts. Bloody mucous stools from acute cases of amebic dysentery usually show quite large *E. histolytica* trophozoites; whereas the trophozoites found in soft stools from mild cases of amebic dysentery are usually smaller in size approaching in size those which give rise to small variety *E. histolytica* cysts.

Cytologically the trophozoites have clear, glass-like ectoplasm and finely granular endoplasm. The motility is usually in a straight line by means of a single large blade-like pseudopodium which moves rapidly and explosively. Usually the nucleus flows into the pseudopodium first, the red blood cells and the finely granular material follow the nucleus into the pseudopodium. In fresh, bloody mucous stools (from acute cases of amebic dysentery) the motility is very rapid. In old stools the motility is more sluggish and the pseudopodia are blunt blade-like.

Precysts—Before encystment the organism becomes round or slightly oval, hyaline (by ridding itself of ingested material), smaller in size, and loses motility completely or it may continue to send out very small blunt pseudopodia. The nucleus consists of a ring of small refractile granules. The precyst secretes a delicate wall and encysts.

Cystic stage—Size 5–20 μ (small variety, 5–12 μ; large variety, 12–20 μ)—The cysts contain 1–4 nuclei, although as many as 8 have been described. The nuclei have characteristic structures—thin nuclear membrane composed of fine granules of chromatin and a very small centrally placed karyosome.

Young cysts have typical chromatoid bodies—rods with blunt ends. These show up best in moist preparations. In iodine stained preparations, brown staining glycogen may be seen. Both the chromatoid bodies and the glycogen disappear when the cysts are old.

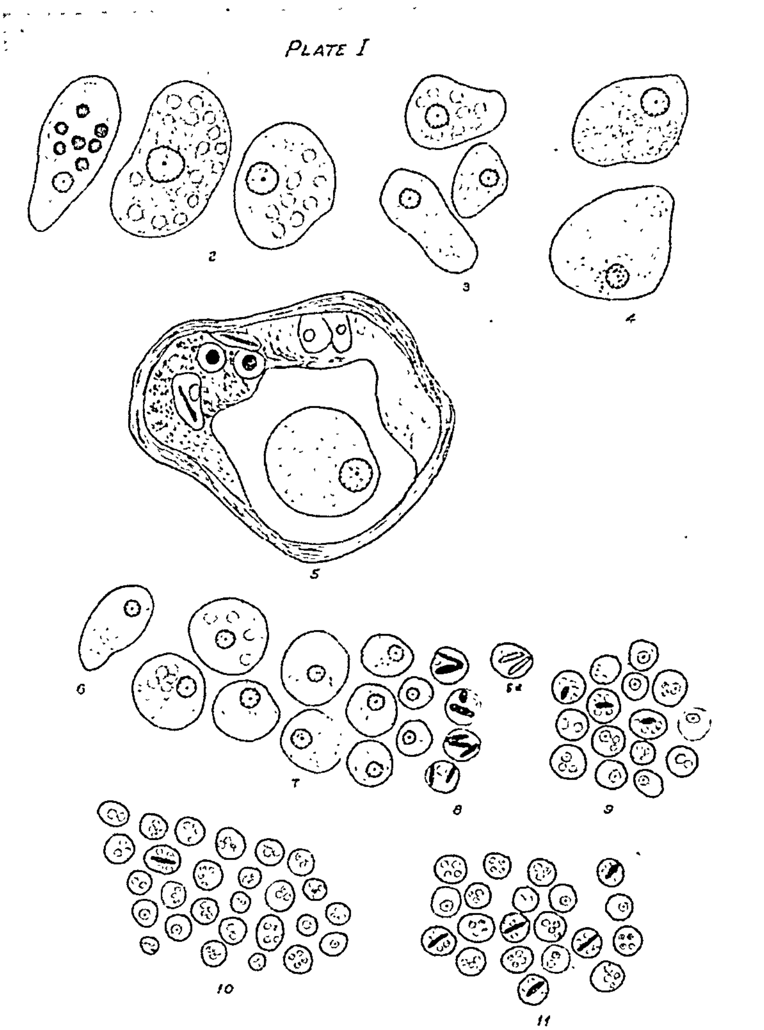

PLATE I, Figures 1–11—*E. histolytica* (Large variety, except for few small cysts, Fig. 10)

Fig. 1. Trophozoite, showing the nucleus and red blood cells (from a bloody mucous stool of an active case, M.) (Red blood cells, chromatin granules and karyosome filled in with India ink to show up better)

Fig. 2. Trophozoites from an iron-hematoxylin preparation

Fig. 3. Trophozoites from a section of an amebic ulcer of the large bowel (iron-hematoxylin stain)

NOTES EXPLAINING THE DRAWINGS

Most of the drawings were made from moist preparations (saline, water, and iodine) of fresh material, with a camera lucida, using a number 10 eye piece and a high, dry, $\frac{1}{6}''$ objective. (Bacteria, crystals, yeast cells, starch grains, red blood cells, karyosomes, chromatoid bodies, and chromatin granules have been filled in with India ink in order that they may show up better.) The oil immersion lens was used in making drawings from sections of tissue and from iron-hematoxylin preparations.

C. *E. Coli* (Plate III, Figs. 24–30)

Trophozoite—The trophozoites vary in size from 15–50 μ, the average size being about 20–25 μ. As a rule there is no differentiation between the ectoplasm and the endoplasm. There are many food vacuoles containing ingested material — bacteria, crystals, starch grains, pus cells, yeast cells, flagellates, and *E. histolytica* cysts. The organism moves sluggishly in one direction for a short distance, halts, produces a pseudopodium from another portion of the body, and moves in another direction, chiefly by changing its shape. Occasionally one encounters very motile *E. coli* which may be confused with *E. histolytica*. In such an event careful examination will reveal ingested debris, bacteria, etc., which does not usually happen with *E. histolytica*. In case of doubt, stained preparations should be made, using the iron-hematoxylin method and the nuclei should be studied carefully. Repeated direct stool examinations should be made, as well as cultures.

Cytologically, the organism contains a visible nucleus surrounded by a thick membrane composed of coarse chromatin granules. The karyosome is fairly large and usually to one side of the center. Chromatin granules are present in the clear zone between the karyosome and the nuclear membrane.

Precystic stage—15–30 μ—In this stage it is frequently difficult to differentiate *E. histolytica* from *E. coli*. As a rule, however, *E. coli* has a thicker wall, the cytoplasm is more granular, and the chromatin granules are coarser.

Cystic stage—10–30 μ (average size 14–20 μ)—The cysts of *E. coli* have fairly thick walls. There are 1–8 nuclei (16–32 have been described). We have seen 12–16 nuclear cysts. The karyosome is usually large and eccentric. The chromatoid bodies are needle- or splinter-like, with sharply pointed ends. Glycogen is present in young cysts. In the single nuclear stage the nucleus is large, becoming progressively smaller with the increase in the number of nuclei.

D. *Endolimax nana* Wenyon and O'Connor, 1917 (1918) (Plate III, Figs. 36 and 37)

Trophozoite — 8–15 μ — The cytoplasm is granular, containing food vacuoles filled with bacteria, yeasts and debris. The motility is by means of short, blunt, hyaline pseudopodia, which are thrown out and withdrawn slowly. In fresh material or in cultures the motility may be by means of slender, finger-like pseudopodia. The nucleus has an indistinct wall without chromatin granules. The karyosome is large and irregular.

Precystic stage—In unstained preparations it is refractile, round, or oval. The cytoplasm is free from vacuoles, bacteria, and debris.

Cystic stage—5–12 μ—In unstained preparations the cysts appear as refractile, colorless, round or oval bodies containing 1–4 nuclei. In stained preparations the characteristics stand out plainly—there are 1–4 nuclei with faint nuclear membranes and no chromatin granules. There is a large central or eccentric karyosome in each nucleus. Glycogen is rarely seen.

E. *Iodameba bütschlii* von Prowazek, 1912; Dobell, 1919 (Plate III, Figs. 31–35)

Trophozoite—5–20 μ or larger (average 10–15 μ)—It is a small ameba moving sluggishly, as a rule, by means of broad, round, and hyaline pseudopodia. In living trophozoites the nucleus is frequently invisible. In well stained preparations, however, the small nucleus (2–3.5 μ) with its large central karyosome, shows up well. The nuclear membrane is usually achromatic. Between the karyosome and the nuclear membrane is a zone filled with gran-

IMPORTANT CRITERIA IN DIFFERENTIATING INTESTINAL AMEBAE

	E. histolytica	*E. coli*	*Endolimax nana*	*Iodameba bütschlii*	*Dientameba fragilis*
Trophozoite Size	18–60 μ 20–35 μ aver.	20–30 μ 15–20 average	6–12 μ 8 average	5–20 μ 10–15 average	10–50 μ
Motility	Active - progressive directional	Sluggish, progressive, not directional	Sluggish, progressive	Sluggish	Active, progressive
Pseudopodia	Finger - shaped, clear, glass-like	Shorter, more blunt, less glass-like	Broad, blunt, not glasslike	Broad, rounded, hyaline	Flat, leaf-like, hyaline
Inclusions	Red blood cells when stools contain blood. No bacteria in fresh stools	No red blood cells. Bacteria, yeasts, crystals, cysts, etc.	No red blood cells, bacteria, debris, etc.	Bacteria, debris, etc.	Bacteria, crystals, debris, etc.
Nucleus	May be invisible	Visible	Visible	Freq. invisible in unstained preparations	Usually visible
Nuclear membrane	Delicate, with single layer of minute chromatin granules in inner surface	Thicker, inner surface lined with coarser chromatin granules	Thin, chromatin rarely seen in inner surface	Thin, but thicker than in *E. histolytica*	Thin, delicate and free from chromatin except in degenerating forms
Karyosome Size	Very small; usually in center of nucleus	Larger, usually eccentric	Large, and may be divided into 1 large and 1 small	Large and central	Large, usually composed of 4 or more deeply staining granules
Intranuclear chromatin	No chromatin between karyosome and membrane	Chromatin granules between karyosome and membrane	Mass situated at one side or in center of nucleus	Frequently small granules of chromatin on inner side of membrane. Linin network between karyosome and membrane	
Cystic Stage Size	5–20 μ	10–20 μ	5–10 μ	5–20 μ	
Shape	Mostly spherical, may be oval or irregular	Spherical, oval or irregular	Spherical, oval or ellipsoidal	Round, oval, rhomboidal, triangular, fusiform	
Nuclei	1–4	1–8	1–4	1, rarely 2	
Karyosome	Minute, central	Larger, eccentric	Large, central or to one side	Large, eccentric, in contact with membrane (signet ring)	
Nuclear Membrane	Delicate	Thicker	Delicate	Thin	
Chromatoid bodies	Bar, oval or rod-like with blunt ends. Present in about 50% of cysts	Splinter- or needle-like; pointed ends. Present in about 10% of cysts	None	None. "Iodophilic" glycogen mass	

ules. When the preparation is well stained the linin network (between the karyosome and the nuclear membrane) shows up. The cytoplasm is homogeneous and finely granular, containing food vacuoles filled with bacteria, crystals and various debris. The glycogen mass is usually large, and stains dark brown with iodine. In iron hematoxylin preparation the glycogen vacuole can be seen.

Precystic stage—In this stage the organism is free from food vacuoles; it appears clear, glassy white and contains a large nucleus. It rounds up, secretes a cyst wall and encysts.

Fig. 62. Cysts (iron-hematoxylin stain) showing nucleus, glycogen, vacuole and volutin granules

Fig. 63. Macrophage from a section of an amebic ulcer of the bowel
Fig. 64. Blastocystis hominis. (It is a vegetable organism, a non-pathogenic fungus, about 5–40μ in diameter. It may be oval or spherical with a narrow band of cytoplasm containing refractile granules and one or more round or oval nuclei surrounded by a delicate membrane. Dividing forms, seen so frequently in cultures, have an hour glass appearance due to the constriction near the center of the cell.)

In hematoxylin stained preparations the narrow band of peripheral cytoplasm is unstained and contains well stained nuclei with large deeply staining karyosomes.

Cystic stage—6–20 μ (average, 9–12 μ)—There is a great variation in shape of the cysts; round, oval rhomboidal, etc. There are one or more glycogen masses staining from pale to mahogany brown with iodine. Other inclusions appear giving staining reactions of volutin. Usually there is only one nucleus, rarely two. The nucleus differs in that the granules are massed at one pole and the karyosome is pressed toward the wall, producing a "signet ring" appearance.

F. Dientameba fragilis Jepps and Dobell, 1918 (Plate II, Figs. 22 and 23)

Trophozoite—Usually described as being small, about 12 μ, but they may be quite large, as large as *E. histolytica*. The organism moves rapidly by means of flattened, leaflike, hyaline pseudopodia. There is differentiation between ecto- and endoplasm. The cytoplasm may be finely or coarsely granular, containing food vacuoles filled with bacteria, yeast cells, starch grains, etc. The most important diagnostic feature is the presence of two nuclei. On dividing, the organism results in two uninucleate individuals, the nuclei of which divide, resulting in binucleate organisms. The nuclei are bounded by fine membranes. The karyosome is usually in the center, but may be at one side of the nucleus. The karyosome is composed of granules, usually only four large, deeply stained, chromatin granules.

V. DIAGNOSTIC PROCEDURE

All stools should be collected in clean, dry containers, free from disinfectants. Oil, bismuth, barium, and medications render the stools undesirable. All stools should be examined as fresh as possible. Soft and bloody mucous stools should be examined immediately or as soon as possible and should never be left over night.

No person should be pronounced negative until 6 stools have been examined on different days. Some of these stools should be obtained normally, and others following the administration of salts. In choosing material for examination, any part of the homogeneous stool and every part of the heterogeneous stool should be examined.

The macroscopic appearance of the stool is significant—whether it is hard, soft, liquid, and whether it contains blood, pus, and cellular exudate. A soft stool, intimately mixed with blood and mucus, containing pus and cellular exudate, is much more indicative of bacillary than of amebic dysentery (F. W. O'Connor), whereas bloody, mucous stools are highly suspicious for amebic dysentery.

Balantidial dysentery due to *Balantidium coli*, a ciliate, is indistinguishable clinically from amebic dysentery. The differential diagnosis must be made by finding the etiological organism.

In alcoholic diarrhea the stools simulate those in amebic dysentery in appearance, but persistent examinations of the stools fail to reveal *E. histolytica* and the patient gets well after several days' rest in bed.

In syphilitic ulcerations of the rectum, the stools may be diarrheal or semi-solid, containing mucus and shreds of tissue. The positive Wassermann test is of diagnostic importance here.

Tuberculous ulceration of the bowel, a common complication of pulmonary tuberculosis, is associated with frequent stools containing mucus and small amounts of blood, except shortly before death, when massive hemorrhages may occur. Finding tubercle bacilli in the stools is of no great importance because a patient with pulmonary tuberculosis may swallow some tubercle bacilli in the sputum.

In chronic mucous colitis there are mucous casts and no blood in the stools. Nonspecific ulcerative colitis, on the

other hand, is associated with frequent stools containing pus, blood, and small amounts of cellular exudate.

In malignant diseases of the bowel the stools are frequent and contain much pus and blood (frequently chocolate in color). The differential diagnosis is based on the laboratory findings, proctoscopic examination, and X-ray findings.

However, whatever the appearance of the stool, a careful examination of at least 4–6 smears should be made before pronouncing it negative. If anything suspicious is seen, a very careful examination should be made, making as many smears as may be necessary. If no decision can be reached, repeated stool examinations should be made by direct examination, by culture, and iron-hematoxylin preparations if necessary.

VI. MICROSCOPIC EXAMINATION

Things necessary for efficient work:

A good microscope

Objectives: Low—2/3″; High dry—1/6″; Oil immersion—1/12″

Oculars—10 is indispensable (4 or 6 may also be of need)

Ocular micrometer—properly calibrated

Good light; artificial is best because it is always the same.

EXAMINATION

Bloody mucous stools from active cases of amebic dysentery—Specimens may be obtained with the proctoscope on proctoscopic examination, by means of a rectal tube, by inserting a glycerin suppository, or normally. A tiny granule of bloody mucus is chosen, placed on a slide, covered with a cover slip and examined under low power first and then under high dry for active *E. histolytica* with red blood cells in them. If the stool should contain fecal material it should be diluted first with a little warm saline to the proper consistency. This is done by placing a drop of warm saline on a slide, a little of the stool is taken on an applicator or needle and emulsified (mixed well) to reading opacity in the drop of saline, covered with a cover slip, and examined as above. The diaphragm of the microscope should be closed as much as possible.

VII. EXAMINATION OF STOOLS FROM CONVALESCENT CASES AND CARRIERS

As the diarrhea of the active cases of amebic dysentery subsides following medication, the feces remains longer in the large bowel, the active amebae lose their motility and begin to round off, giving rise to precysts. The precysts of *E. histolytica* are 20–30 μ in diameter, hyaline in appearance, and are free from granular material, or contain only very fine granular material (the remains of the red blood cells). The nucleus is typical, containing a small central karyosome, and is bounded by a fine membrane composed of fine chromatin granules. In this stage it is sometimes difficult to diagnose *E. histolytica*. Such stools may be cultured (on liver infusion, agar overlaid with serum, saline, described later), whereupon the precysts vegetate, giving rise to typical *E. histolytica* trophozoites. If difficulty is still encountered, the examinations should be repeated on normal stools as well as those following salts. Iron-hematoxylin preparations might also be made and examined for typical *E. histolytica* with the oil immersion lens.

As the stools remain longer in the large bowel they become more formed and the amebae encyst, giving rise to cysts containing 1–4 nuclei.

Formed stools from convalescent cases or from carriers should be examined with warm water or saline as well as with iodine. (The iodine solution should be fresh—a 1 per cent aqueous solution of iodine in 2 per

cent potassium iodide, or an aqueous solution of 5 per cent potassium iodide saturated with iodine and diluted with an equal part of distilled water for use. This should be kept in a brown bottle and away from the light, or a card may be wrapped around the bottle to keep the iodine solution from disintegrating.)

In making smears a drop of saline or water is placed on a slide. In this is emulsified a small amount of feces, with a needle or applicator, to reading opacity, covered with a cover slip, and examined first with the low power and then with the high dry (some people prefer to use the oil immersion lens). In such smears may be seen flagellates, amebae, ova, larvae of such worms as *Strongyloides*, etc. In young cysts the chromatoid bodies show up very clearly in the water or saline preparations. Several smears of each specimen should be examined with saline or water, as well as with iodine. In the iodine preparations iodine instead of water or saline is used and smears made and examined exactly the same as above. The iodine kills the protoplasm and stains the cytoplasm more or less yellow, the cyst and nuclear walls dark, and the glycogen dark brown. As a rule, the karyosomes stand out as refractile bodies. Thus one can study the number and type of nuclei, thickness of the cyst wall, type and position of the karyosome, etc. Iron-hematoxylin permanent preparations are unnecessary unless finer details are desired to study.

VIII. Examination of Pus from Liver and Lung Abscesses

In examining pus from liver and lung abscesses one should look for active *E. histolytica*, for they do not encyst in pus. *E. histolytica* are found in the walls of abscesses and not in the central necrotic material, so that care should be taken to procure material from the walls of such abscesses in examining for *E. histolytica*.

In case of doubt as to the diagnosis of an intestinal protozoan, or if permanent preparations are desired for other reasons, the following method has been found to work the best: The material should be perfectly fresh, properly fixed, and at no time in the process should the slide or cover slip preparations be permitted to dry; as soon as that happens the preparations are ruined and should be discarded. Bloody mucous or soft stools need not be diluted, but hard stools should be diluted with saline before making smears. Smears may be made on slides or cover slips, using an applicator. Smears should be uniform and not too thick. If slides are used, the fixing fluid should be placed in staining jars. If cover slips are used, the fixing fluid is placed in Petri or evaporating dishes. Smears of the proper thickness are made and the cover slips are immediately dropped film side downward into the fixing fluid and are permitted to float for a few moments, then they are picked up with forceps and completely immersed face upward, using plenty of fixative and discarding it when through.

Procedure for Fixing and Staining (Iron-hematoxylin Method)

Fixing solution—Schaudinn's solution

Saturated solution of mercuric chloride in distilled water.. 2 parts
95% alcohol . . . . 1 part

To every 100 c.c. of this mixture add 2–5 c.c. glacial acetic acid

Fix 10–20 minutes (30 minutes is better for cysts)

Wash and harden

50% alcohol for a few minutes

To remove fixation, 70% alcohol to which a few drops of iodine solution (alcoholic) has been added, for at least 10 minutes. The iodine removes the remaining $HgCl_2$.

95% alcohol (best for an hour or several days)

Hydrate

70% alcohol for a few minutes

50% alcohol for a few minutes
30% alcohol for a few minutes
Distilled water

Stain (Iron-hematoxylin method)

Mordant by placing in 2% aqueous iron alum (ammonium ferric sulphate) 2–6 hours
Wash in distilled water for a few seconds
Stain in 0.5% ripened solution of hematoxylin in distilled water 6–24 hours. (Make up solution, place in flask, plug with cotton wool, place in a warm place —in the sun, if possible—shaking from time to time. When the solution is "ripe"—a good brown color, namely the hematoxylin is more or less oxidized to hematein, it is ready for use. This may require several weeks.)
Wash in distilled water
Differentiate in 0.5 to 1% aqueous iron alum (never permitting the preparation to dry during the process). Remove a slide, rinse in distilled water, and examine under the microscope for proper differentiation; the cytoplasm should be gray; the cyst, nuclear walls, as well as the chromatoid bodies and karyosomes, should be black when properly decolorized.
Wash in distilled water
Then in running tap water for at least ½ hour in order to wash out all the alum; otherwise the decolorization will continue
Wash in distilled water

Dehydrate

50% alcohol 5 minutes
70% alcohol 5 minutes
95% alcohol 5 minutes
Absolute alcohol 10 minutes, 2 changes
(Absolute alcohol and xylol, 50–50, 5 to 10 minutes)

Clear (Xylol 5 minutes)
Mount in balsam.

IX. CONCENTRATING STOOLS FOR CYSTS

A number of methods may be used in concentrating specimens for cysts when these are present in small numbers. One method is to take a small piece of the stool, emulsify it well in water or saline, strain through two layers of gauze, centrifuge at moderate speed 2 or 3 minutes, pour off the supernatant fluid, emulsify the sediment as before, and repeat the washing 2 or 3 times. Examine the final sediment with water and iodine.

Another method is to emulsify a small piece of feces with distilled water, place it in a 500 c.c. graduate, make up to 500 c.c. with distilled water, mixing well. Let it stand for 20 to 30 minutes, pour off the supernatant fluid and replace with distilled water, mix well and let stand over night. Then examine the sediment with water and iodine solution.

X. CULTURAL METHODS

At times cultures are of great assistance in making a diagnosis because precysts, cysts, and atypical trophozoites become typical trophozoites showing the characteristic morphology and motility. However, the cultures must be made properly and carefully, using proper media, aseptic methods, and examining at the proper time. Cultures should not be relied upon entirely because our experience during the Chicago epidemic has taught us that only about 5–8 per cent of the small variety *E. histolytica* grow in the culture medium used for the large variety. The presence of arsenic and other amebicides prevent *E. histolytica* from growing. Routine cultures are unnecessary in making a survey.

MEDIA

Cleveland and Collier (*Liver infusion agar*)

This medium is one of the best for practical diagnostic purposes. The medium consists of slants of liver infusion agar.

30 gm. liver infusion agar (Digestive Ferments Co., Detroit, Mich.)
3 gm. dehydrated sodium phosphate
1,000 c.c. distilled water
Dissolve, tube about 5 c.c. per tube, sterilize 15 lb. for 30 minutes, slant and keep in the ice box until shortly before using.

Before making inoculations these slants are overlaid with sterile serum saline 1–6. (Wassermann negative hu-

man inactivated serum, horse or rabbit serum, etc., may be used by taking 1 part of serum to 6 parts of NaCl, filtering through a sterile Berkefeld filter, incubating 24–48 hours to test sterility. If sterile, place in the ice box until shortly before using.)

The slants and serum saline should be placed in the incubator for a couple of hours before using in order to bring the temperature up to body temperature. Sterile precautions should always be used in making the cultures. Before making inoculations the slants are overlaid (sterilly) with sterile serum NaCl, 1–6. A little sterile rice starch or rice flour may be added, but is not necessary. If the stool is soft, watery, or bloody mucus, a little is inoculated, using a sterile pipette or needle. If the stool is solid, a loopful is inoculated, macerating well by rubbing with the needle against the sides of the tube. Incubate at 37.5° C., and examine after 24 and 48 hours. Cultures should not be examined prematurely because occasionally *E. coli* grows in this medium, and in young cultures when rapid division takes place the nuclear structure may not be typical, the motility rapid; so that one may have difficulty in differentiating *E. histolytica* from *E. coli*. Occasionally sub-cultures are necessary in order to decide as to whether an organism is *E. histolytica* or *E. coli*. In 24–48 hour cultures, even when *E. coli* is present, it shows its typical characteristics—thick wall, sluggish motility, the entire organism seems to roll about in its wall. *E. histolytica*, on the other hand, has a thin wall and moves rapidly by means of a pseudopodium in an elongating, slug-like manner.

"Mature living *E. histolytica* cysts do not all hatch simultaneously nor at the same rate; some hatch quickly, others slowly. They usually begin to hatch after 2¼ hours' incubation. Cysts which do not hatch after 12 hours' incubation usually perish. Occasionally some hatch after 20 hours' incubation. Cysts begin to hatch when the chromatoid bodies and glycogen disappear." C. Dobell, *Parasit.* XX, 4:383, 1928.

All other intestinal amebae do not grow as readily in this culture medium and cannot be maintained in culture as long as *E. histolytica*. When the other intestinal amebae grow in this culture medium they show their typical characteristics and should not be confused with *E. histolytica*.

In order to keep strains of *E. histolytica* going, make sub-cultures every 48 hours (using sterile precautions). A little sterile rice flour or rice starch is added to the liver infusion agar slant overlaid with serum saline before making the inoculations. To make the sub-cultures, use a sterile pipette with a good sized bore and transfer a little of the sediment, taking as little of the supernatant fluid as possible. Some strains of *E. histolytica* grow readily, while others grow with great difficulty.

Locke Serum Medium of Craig

This medium consists of a mixture of a modified Locke solution and inactivated human, horse or rabbit serum. The serum used should not be over 48 hours old.

Locke solution:

Sodium chloride	9.0	gm.
Calcium chloride	0.024	gm.
Potassium chloride . .	0.42	gm.
Sodium bicarbonate. .	0.20	gm.
Distilled water	1,000	c.c.

Filter and autoclave 15 lb. 15 minutes

Medium:

1 part inactivated (56° C. ½ hour) serum to 7 parts Locke solution
Filter through a Berkefeld filter
Tube 10 c.c. per sterile tube
Incubate 24–36 hours to test sterility
Keep in incubator until used.

A slight amount of sterile rice starch or rice flour increases the efficiency of this medium.

XI. COMPLEMENT-FIXATION IN THE DIAGNOSIS OF AMEBIASIS AND AMEBIC DYSENTERY

The technic is practically the same as that used in the standard method for the complement-fixation of syphilis in the United States Army laboratory fully described in Craig's "The Wassermann Test" (1920), except that the specific amebic antigen is used. The anti-human as well as the anti-sheep system may be used.

Reagents needed:

The blood serum to be tested is inactivated in a water-bath at 56° C. for ½ hour.

Antigen—alcoholic extract of sediment of cultures of *E. histolytica*.

Antigen Control—prepared exactly the same way as the test antigen except that the bacteria growing in association with the *E. histolytica* are used.

Amboceptor—anti-human or anti-sheep, as the case may be.

Complement Guinea Pig Serum:

Red blood cells—type 4 (Moss) human or sheep cells (whatever system is used).

Set up of test:

Front and rear tubes

Place 0.9 c.c. NaCl in each tube

Test 0.1 c.c. unknown serum in front and rear tubes

0.1 c.c. + serum in front and rear tubes

0.1 c.c. — serum in front and rear tubes

1 unit antigen to front tubes

2 units complement to each tube

Incubate—water-bath 37.5° C. ½ hour

Add 0.5 c.c. 3% cells (Craig uses 0.1 c.c. of 5%)

Add 2 units amboceptor

Incubate 37.5° C. water-bath for 1 hour

Shake every 15 minutes

Place in ice box for 2 hours and read. Readings are made as follows: 4+, 3+, 2+, + and ±, according to the degree of inhibition of hemolysis.

Any reaction below 3+ should not be considered diagnostic unless the patient has been treated. Upon treatment the complement-fixation becomes negative.

The complement-fixation test is still in the experimental stage and one may use the test only as an aid and not as an absolute criterion in making a diagnosis. As little as one injection of emetine hydrochloride will change a positive complement-fixation reaction to negative when the stools may still show motile amebae.

BERTHA KAPLAN SPECTOR,
Referee

Tentative Methods for the Serological and Bacteriological Procedures in the Diagnosis of Enteric Fevers*

The report submitted to your committee in 1934 outlined the fundamental procedures recommended as aids in the diagnosis of enteric disease. These were based upon reports in the literature, information obtained by means of questionnaires sent to directors of laboratories representative of various sections in the United States and Canada, and personal experience. The outline was published in the *Year Book* of the Association in the hope that persons other than those who had received the questionnaire would submit comments and criticisms. While the response has been limited, the data now available would seem sufficient to warrant the inclusion of details of technic in the outline previously prepared.

Appended to the 1934 report was a list of problems which seem particularly vital to the development of the most efficient and reliable methods employed as aids in the diagnosis of enteric disease. Considerable interest has been shown by certain investigators, and in some instances contributions have been made. However, as would be expected, there was lack of uniformity in the studies undertaken by the various workers and in the type of data furnished. It is suggested, therefore, that a selected group of laboratories be invited to participate in a coöperative investigation of at least certain of the problems, in which a carefully planned mode of procedure would be followed.

The problems previously suggested for coöperative study are listed for reference.

PROBLEMS FOR COÖPERATIVE STUDY

SEROLOGICAL PROCEDURES

I. Comparison of various types of suspension for demonstrating the granular type of agglutination with *B. typhosus*.

II. Study of the diagnostic significance of macroscopic agglutination tests with suspensions of: (1) *B. paratyphosus* A, (2) *B. paratyphosus* B, (3) *B. dysenteriae*, and (4) other mem-

* Report of the Referee on Methods and Reagents for the Diagnosis of Enteric Fever for the Standard Methods Committee on Diagnostic Procedures and Reagents.

bers of the enteric disease group in patients' sera.

III. Selection of standard strains for the tests mentioned in I and II.

IV. Study of other serological tests, for example, complement-fixation and precipitation tests, in the diagnosis of enteric disease.

BACTERIOLOGICAL PROCEDURES

I. Selection of the optimum preservative for fecal and urinary specimens when the bacteriological examination for microörganisms of enteric disease cannot be undertaken immediately after collection.

II. Determination of the etiological significance of species concerning which there is, at present, difference of opinion, for example, *B. morgani* No. 1, *B. alkalescens, B. dispar*, etc.

III. Establishment of criteria for the most rapid and accurate identification of species, particularly those belonging to the dysentery and paratyphoid-enteritidis group.

SEROLOGICAL PROCEDURES

EXAMINATION OF SERUM FOR AGGLUTINATION WITH B. TYPHOSUS

I. *The outfit*—Use a sterile, tightly stoppered or sealed, glass container with a capacity of from 10 to 15 c.c., in a mailing case conforming to the postal laws and regulations.

II. *Preparation of the specimen*—Remove the serum with a sterile pipette (a capillary pipette fitted with a small rubber bulb may be used) with precautions to prevent contamination of the clot, which should be reserved for bacteriological examination. Centrifugalize to remove the blood cells.

Results obtained with hemolyzed sera should be considered of questionable significance, since certain conditions which produce hemolysis may also affect the agglutinative properties. The clots from such specimens should be cultured. The hemolysis may be due to the development of the bacteria which were present in the blood stream.

III. *Dilutions*—Prepare the following dilutions of the serum in 0.85 per cent solution: 1:10, 1:20, 1:40, 1:80, 1:160, and higher if desired.

IV. *Agglutinating suspensions*—Employ at least two suspensions of uniform turbidity; one to demonstrate floccular and the other, granular agglutinative properties.

Preparation of Formalin-Treated Suspension to Demonstrate Floccular Agglutination — Employ a "smooth," actively motile strain of *B. typhosus*. Streak a freshly poured plate of beef-infusion agar containing no water of condensation. If, after from 18 to 20 hours' incubation at from 35 to 37° C., other than perfectly "smooth" colonies are noted, suspend two or three of the latter in small amounts of salt solution or broth and replate immediately. Repeat this process until an entirely "smooth" culture is obtained. Check the purity of the culture by microscopic examination, by determining the reaction in double-sugar medium and agglutination in *B. typhosus* anti-serum. Use a suspension of a 24 hour beef-infusion agar culture to inoculate 2 per cent beef-infusion agar in pint Blake or other bottles which will give adequate surface. If water of condensation is present on the agar, remove it with a pipette before inoculation. After from 18 to 20 hours' incubation at from 35 to 37° C., pipette into each pint Blake bottle or its equivalent 10 c.c. of 0.85 per cent salt solution containing 2 per cent of formalin and suspend the growth in this. Make Gram-stained preparations and discard suspensions which show the presence of contaminating microorganisms. Pool the suspensions in a sterile bottle; place in the refrigerator; and after 48 hours, prepare sub-cultures. Hitchens's medium is recommended for this purpose since it provides conditions favorable to both aerobic and anaerobic microörganisms.

Should growth of *B. typhosus* occur, retest, after additional refrigeration, until no evidence of viability is obtained. If considerable material settles out, decant the supernatant suspension into a fresh bottle. Adjust the suspension to a turbidity 10 times that of barium-sulphate * standard No. 3 [1] and a formalin content of 2 per cent. Determine the opacity of the suspension by comparison of diluted portions with barium-sulphate standard No. 3 and with a similar suspension previously standardized. Calculate the required amount of diluents as in the following example:

Assuming that 400 c.c. of concentrated suspension are to be adjusted and it is found that this needs to be diluted 1:12 to equal barium-sulphate standard No. 3, then:

$$\frac{400 \times 12}{10} = 480 \text{ c.c.—volume adjusted suspension}$$

or 80 c.c. of salt solution containing 2 per cent formalin are required to be added to 400 c.c. of the original suspension.

For agglutination tests, dilute with 9 parts of 0.85 per cent salt solution, thus obtaining a suspension equivalent in turbidity to barium-sulphate standard No. 3 and containing 0.2 per cent formalin.

Test the agglutinability of the suspension in comparison with a previous lot which has proved satisfactory, using, if possible, a series of human sera giving various degrees of agglutination as well as antisera produced in animals. Store in a refrigerator.

Preparation of Alcohol Treated Suspension [2] *to Demonstrate Granular Agglutination*—Employ a "smooth" strain of *B. typhosus,* preferably one which is nonflagellated. Follow the procedure outlined for the formalin treated suspension to insure smoothness and purity of the culture and inoculate the agar in pint Blake or other bottles. After from 18 to 20 hours' incubation, pipette into each pint Blake bottle or its equivalent 10 c.c. of 0.85 per cent salt solution containing 0.5 per cent phenol and suspend the growth. Make Gram-stained preparations and discard suspensions which show the presence of contaminating microörganisms. Measure the suspension in a sterile graduate and pool it in an Erlenmeyer flask. Add alcohol to give a concentration of 33.3 per cent. The volume of 95 per cent alcohol required equals the volume of the suspension multiplied by 0.54, a constant obtained from the formula:

$95\ x = 33.3\%$ (volume of the suspension $+\ x$) in which $x =$ the volume of 95 per cent alcohol which will be required

Rotate the flask slowly as the alcohol is added or stir with a sterile glass rod. Pour the alcohol treated suspension into sterile cylinders and incubate over night at from 35 to 37° C. The following morning, decant the supernatant suspension from the sediment into a sterile bottle, mix thoroughly, and prepare sub-cultures to determine the presence of contaminating microorganisms. Hitchens's medium is recommended for this purpose since it provides both aerobic and anaerobic conditions.

Adjust the turbidity of the suspension to 10 times that of barium-sulphate standard No. 3 and its alcohol content to 30 per cent. Determine the opacity of the suspension by comparison of diluted portions with barium-sulphate standard No. 3 and with a similar suspension previously standardized. Calculate the required volume of diluents as in the following example:

Assuming that 400 c.c. of suspension are to be adjusted and that this needs

* Silica or other standards of equivalent opacity may be employed.

to be diluted 1:12 to obtain the required density, then:

$\frac{400 \times 12}{10} = 480$ c.c.—volume of adjusted suspension and 80 c.c.—total volume of diluent required

$480 \times 30\% = 144$ c.c.—total volume of 100 per cent alcohol required

$400 \times 33.3\% = 133.3$ c.c.—volume of alcohol already in suspension

$144 - 133.3 = 10.7$ c.c.—volume 100 per cent alcohol to be added

$10.7 \times \frac{100}{95} = 11.3$ c.c.—volume of 95 per cent alcohol required

80 c.c. $- 11.3$ c.c. $= 68.7$ c.c.—volume of 0.85 per cent salt solution containing 0.5 per cent phenol to be added.

For agglutination tests, dilute with 9 parts of 0.85 per cent salt solution, thus obtaining a suspension equivalent in turbidity to barium-sulphate standard No. 3 and containing 3 per cent alcohol and 0.05 per cent phenol.

Test the agglutinability of the suspension in comparison with a previous lot which has proved satisfactory, using, if possible, a series of human sera giving various degrees of agglutination as well as antisera produced in animals. Store in a refrigerator.

V. *The test*—Combine equal parts (from 0.3 to 0.5 c.c. recommended) of serum dilutions and suspensions in small, clear glass tubes (11 mm. x 75 mm. is a convenient size), and shake thoroughly. For purposes of control, combine equal parts of each suspension and (a) 0.85 per cent salt solution and (b) specific dilutions of homologous antiserum. Incubate for from 18 to 20 hours at approximately 50° C.*

VI. *The reaction*—Record the degree of reaction as follows:

4+ = clear supernatant fluid—complete agglutination
3+ = clear supernatant fluid—definite agglutination
2+ = cloudy or slightly cloudy supernatant fluid—definite agglutination
+ = cloudy supernatant fluid—agglutination discernible to the unaided eye
± = questionable reaction
− = uniformly turbid suspension—no agglutination

VII. *The report*—Either of the following methods may be employed.

First method

A. Report that definite agglutination occurred—

1. When both granular and floccular agglutination (3+ or 4+) is obtained in a 1:80, or higher, dilution.
2. When either granular or floccular agglutination (3+ or 4+) is obtained in a 1:160, or higher, dilution.

B. Report that partial agglutination occurred—

1. When reactions less than those reported as definite agglutination are obtained, provided agglutination (3+ or 4+) of one or both types occurs in a 1:40 dilution.

C. Report that agglutination of diagnostic significance did not occur—

1. When reactions less than those regarded as partial are obtained.
2. When no agglutination is obtained.

or

Second method

A. Report the dilution of serum in which each type of agglutination is obtained.

In case either granular or floccular agglutination alone occurs, add one of the following statements to the report or write a letter to the physician relative to the significance of the reaction.

"Floccular but not granular agglutination occurred. This type of reaction is occasionally obtained in sera from patients having typhoid fever but is more often observed in blood from typhoid carriers or those who have re-

* This should not vary more than 2° below or above 50° C.

ceived typhoid vaccine. If the individual is ill or there is evidence that he may be a typhoid carrier, fecal specimens should be submitted for bacteriological examination."

or

"Granular but not floccular agglutination occurred. This type of reaction is observed in sera from a small percentage of patients having typhoid fever but may be obtained when there is an infection with a microörganism antigenically related to *B. typhosus*. Therefore, fecal specimens should be submitted for bacteriological examination."

EXAMINATION OF SERUM FOR AGGLUTINATION WITH B. PARATYPHOSUS A AND B

The procedure outlined for *B. typhosus* may be followed. However, the relatively low incidence of infections with microörganisms of the paratyphoid-enteritidis group in this country and the variety of species involved render the agglutination test of questionable practical value for use as a routine procedure.

BACTERIOLOGICAL PROCEDURES FOR THE ISOLATION OF BACILLI INCITING ENTERIC DISEASE

EXAMINATION OF BLOOD

I. *The outfit*—Use a sterile, tightly stoppered or sealed, glass container with a capacity of from 10 to 15 c.c., in a mailing case conforming to the postal rules and regulations.

II. *Preparation of the specimen*—Remove the serum with a sterile pipette, using precautions to prevent contamination of the clot. Reserve the serum for serological tests.

III. *Cultural examination*—Transfer the clot to 8 or 10 c.c. of bile medium (Conradi's modified). Sub-culture after from 40 to 48 hours' incubation at from 35 to 37° C. and at intervals thereafter for at least 3 weeks, unless bacterial incitants of enteric disease are isolated sooner.

EXAMINATION OF FECES AND URINE

I. *The outfit*

A. Use a tightly stoppered or sealed, glass tube or jar, with a capacity of from 20 to 30 c.c. in a mailing case conforming to the postal laws and regulations. The tube or jar should contain from 8 to 10 c.c. of 30 per cent glycerol in 0.6 per cent salt solution.

B. Give instructions for the collection of the specimens, printed either on the history form or on a separate slip included in the outfit.

C. Provide a swab or wooden spoon, for the collection of feces, of which about 1 gm. should be added to from 8 to 10 c.c. of glycerol solution.

D. From 8 to 10 c.c. of urine should be added to from 8 to 10 c.c. of glycerol solution.

NOTE: When specimens of feces or urine can be examined within a very short time (1 or 2 hours) after collection, and when urine has been collected aseptically, the use of a preservative is, of course, unnecessary.

II. *Plating*

A. *Feces*—If undiluted feces is submitted, combine 1 part with from 8 to 10 parts of fluid medium, preferably 30 per cent glycerol solution, and allow it to stand for from 10 to 15 minutes so that the coarse particles will settle. Use not less than 4 plates, at least 1 of which shall contain medium favorable to the development of dysentery bacilli (eosin-methylene-blue agar or a modification of Endo's agar) and another, that which is inhibitory to *B. coli* but favorable to typhoid and paratyphoid bacilli (Krumwiede's brilliant-green agar). Usually, the amount of fecal suspension which can be transferred with a loop 4 mm. in diameter on each plate will give well isolated colonies. Streak the material on each plate with a large wire loop, bent wire needle or sterile glass rod. Incubate the plates for from 18 to 20 hours at from 35 to 37° C.

B. *Urine*—Streak the specimen as received on one plate of eosin-methylene-blue or Endo's agar and one of brilliant-green agar. Add from 2 to 3 c.c. of the remainder to from 8 to 10 c.c. of bile medium (Conradi's modified). Incubate the latter for from 18 to 20 hours at from 35 to 37° C. and streak one plate of eosin-methylene-blue or Endo's agar and one of brilliant-green agar.

For purposes of control, streak portions of each type of plating medium with cultures of *B. typhosus*, *B. paratyphosus* A and B, *B. dysenteriae*, and *B. coli.*

CRITERIA FOR IDENTIFICATION OF SPECIES

The criteria for identification of bacterial incitants of enteric disease and other Gram-negative bacilli found in feces have, for convenience, been summarized in Table I. The procedures necessary to determine the significant characteristics will be discussed separately.

I. *Colonial characteristics*—These should be considered only as a means for selecting those colonies from which sub-cultures are to be made. If a tentative report seems essential, a suspension of microörganisms from a colony may be tested for agglutination in a loopful of a dilution of antiserum on a glass slide, but a final report should be based on adequate criteria for identification of the species.

II. *Differential media for sub-cultures*—Pick characteristic colonies to Russell's double-sugar medium. Stab the butt and streak the surface of the slant. Record the reactions after incubation for from 18 to 20 hours at from 35 to 37° C. (For purposes of control, inoculate tubes of this medium with standard strains of *B. typhosus*, *B. paratyphosus* A and B, *B. dysenteriae*, and *B. coli.*)

III. *Morphology*—Prepare films on glass slides or, if slide agglutination tests are performed, allow these preparations to dry and then fix them and stain by Gram's method. All the microörganisms listed in Table I are relatively small, evenly staining, Gram-negative bacilli without spores. If the stained preparations show any evidence of contamination, streak the culture on blood agar as well as Endo's agar since the contaminating microörganism may be inhibited on the latter. Prepare a hanging drop to study the motility. Transfer one loopful of a 1 to 3 hour broth culture to a cover slip and invert over it a hollow-ground slide which has been ringed with vaseline. Examine with a high-power dry objective.

IV. *Macroscopic slide agglutination test*—Transfer to a glass slide one loopful of appropriate antiserum diluted as indicated by previous standardization and a loopful of a corresponding dilution of serum from a normal animal of the species used for the production of the antiserum. Transfer, with a small loop, growth from a colony on the plating medium or from Russell's double-sugar agar to the normal serum and after emulsifying, transfer a loopful to the antiserum. Tilt the slide slowly and observe over a black background for clumping.

A report should not be based on the results of this test unless the species indicated has been isolated from a previous specimen from the same patient. The test may be very useful, however, in the selection of antisera in which to perform macroscopic tube agglutination tests.

V. *Macroscopic tube agglutination test*—Inoculate beef-extract broth from the double-sugar slant and incubate at from 35 to 37° C. (usually from 2 to 4 hours) until the turbidity is equivalent to that of barium-sulphate standard No. 3, or suspend the growth from a beef-extract or beef-infusion agar

TABLE I

CRITERIA FOR IDENTIFICATION OF BACTERIA INCITING ENTERIC DISEASE AND OTHER GRAM-NEGATIVE BACILLI FOUND IN FECES*

Species	Reaction in double-sugar medium	Reaction in media containing: Dextrose	Maltose	Mannitol	Lactose	Saccharose	Xylose	Rhamnose	Dulcitol	Motility	Indol production	Reaction in litmus milk	Serological reaction
B. typhosus	+†	A	A	A	—	—	$\overline{A}$	—	$(\overline{A})$	Motile[1]	Not produced	A ± – or Alk ±	Agglutination in *B. typhosus* antiserum
B. dysenteriae Shiga	+	A	$\overline{A}$	—	—	—	—	—	—	Nonmotile	Not produced	A ± – or Alk ±	
Schmitz	+	A	$\overline{A}$	—	—	$\overline{A}$	—	A	—	Nonmotile	Produced	A ± – or Alk ±	Agglutination in polyvalent and/or monovalent antisera for members of the group
Flexner°	+	A	$\overline{A}$	A	—	$\overline{A}$	—	$(\overline{A})$	$(\overline{A})$	Nonmotile	Variable	A ± – or Alk ±	
Sonne	+	A	A	A	–A	–A	—	A	—	Nonmotile	Not produced	A or AC	
B. dispar	+	A	A	A	–A	$\overline{A}$	$\overline{A}$	$\overline{A}$	$\overline{A}$	Nonmotile	Produced	A or AC	Of questionable value
B. alkalescens	+	A	A	A	—	—	A	A	A	Nonmotile	Produced	Alk or A to Alk	Agglutination in *B. alkalescens* antiserum
B. paratyphosus A	⊕	AG	AG	AG	—	—	—	AG	AG	Motile[1]	Not produced	A or Alk	Agglutination in, and absorption of, agglutinative properties from *B. paratyphosus* A antiserum
Paratyphoid-enteritidis group‖	⊕	AG	AG	AG	—	—	AG (—)	AG	AG (—)	Motile[1]	Not produced	A to Alk	Agglutination in polyvalent and/or monovalent antisera for members of the group. Absorption of agglutinative properties is necessary for the identification of species.
B. morgani No. 1	⊕	AG	—	—	—	$\overline{AG}$	—	—	—	Motile[1]	Produced	– or Alk	Of questionable value
B. coli	⊕	AG	AG	AG	AG	$\overline{AG}$	AG	AG	AG	Motile[1]	Produced	AC	Of questionable value

* Only those species which do not liquefy gelatin are included. Variations, especially in fermentative properties, which have not been indicated may be occasionally encountered, particularly after long cultivation on artificial media.

† Occasionally acid throughout.

[1] Nonmotile strains sometimes found, especially when freshly isolated.

° The mannitol-fermenting group.

‖ *B. paratyphosus* B, *B. enteritidis* and other closely related species.

\+ = Acid butt, neutral or alkaline slant, no gas.

⊕ = Acid and gas in butt, neutral or alkaline slant.

⊕ = Acid and gas throughout.

A = Acid.

– = No perceptible change. –A = Acid produced slowly. AG = Acid and gas.

$\overline{A}$ = No change or acid. $(\overline{A})$ = Usually no change, occasionally acid.

AG (—) = Usually acid and gas, occasionally no change.

$\overline{AG}$ = No change or acid and gas.

A ± = Weak acid.

Alk = Alkaline.

Alk ± = Weak alkaline.

AC = Acid and coagulation.

slant which has been incubated for from 18 to 20 hours, in 0.85 per cent salt solution making the turbidity equivalent to that of barium-sulphate standard No. 3. Combine 0.3 c.c. amounts of either of these and of appropriate antisera diluted as indicated by previous standardization. For purposes of control, combine 0.3 c.c. amounts of each culture to be tested with salt solution and of dilutions of each antiserum with a suspension of its homologous species. Incubate the tests at from 35 to 37° C. for 2 hours and then leave in the refrigerator over night before reading, except in the case of *B. alkalescens* and *B. dysenteriae* Sonne. Incubate tests for identification of these two species at approximately 50° C. for from 18 to 20 hours and read. Follow the procedure outlined under serological procedures for recording the degree of reaction.

VI. *Fermentative properties*—Inoculate carbohydrate peptone water containing Andrade indicator and observe at frequent intervals during 14 days' incubation at from 35 to 37° C. Test this medium each time a new lot is prepared with standard strains of the species included in Table I. When there is any doubt concerning the production of gas, inoculate dextrose broth in a Durham fermentation tube and observe at intervals during 1 week's incubation at from 35 to 37° C. Incubate one tube of the same lot of medium inoculated with *B. coli* and one uninoculated and observe at the same time as the culture being studied. When gas production is to be determined from carbohydrates which are easily hydrolyzed by heat, use medium sterilized by filtration distributed in Smith fermentation tubes.

VII. *Production of indol*—Inoculate a tube of Dunham's peptone water with the culture to be tested and incubate for 4 days at from 35 to 37° C. Incubate at the same time one tube of this medium inoculated with *B. coli*, one with *B. typhosus*, and one uninoculated. Add 1 c.c. of ether to each and mix well by rotating the tubes. Allow a few drops of Ehrlich's reagent to run down the side of the tube to form a layer between the ether and the peptone water. A definite ring varying from rosy pink to deep red indicates the presence of indol.

VIII. *Liquefaction of gelatin*—Transfer the culture with a needle, stabbing the medium to the bottom of the tube. Incubate at from 35 to 37° C. for 2 weeks unless evidence of liquefaction is observed sooner. To determine liquefaction, immerse the tube in ice water or leave it in the refrigerator for 30 minutes.

IX. *Reaction in litmus milk*—Inoculate a tube of litmus milk with the culture to be tested and record the reaction at frequent intervals during incubation at from 35 to 37° C. for 14 days. For purposes of comparison, incubate at the same time an uninoculated tube of the same lot of litmus milk.

X. *Absorption tests*—Occasionally, when the results of agglutination tests are indefinite or when cross-agglutination is obtained, it is necessary to employ absorption tests to determine the species.

Combine equal parts of a dilution of antiserum and (a) a suspension of the homologous species and (b) a suspension of the unidentified culture grown for from 18 to 20 hours at from 35 to 37° C. on beef-infusion agar. The serum dilution and the turbidity of the absorbing suspensions are determined by standardization. Incubate the mixtures for 3 hours at approximately 50° C., inverting the tubes occasionally to insure contact of serum and microörganisms. Leave them in the refrigerator over night and centrifugalize at high speed for 1 hour

or until the supernatant fluid is clear. Prepare dilutions of the supernatant fluid, and combine 0.3 c.c. of each with 0.3 c.c. of a suspension in 0.85 per cent salt solution (comparable in turbidity to barium-sulphate standard No. 3) of (a) the species homologous to the serum used and (b) the culture to be identified. Incubate the tests at from 35 to 37° C. for 2 hours and leave them in the refrigerator over night before reading the reactions. Incubate tests with absorbed *B. alkalescens* and *B. dysenteriae* Sonne antisera at approximately 50° C. for from 18 to 20 hours and read.

For control purposes, perform tests, at the same time, with sera which have not been subjected to absorption.

It may be unnecessary to study all of the characteristics listed in Table I, but when a strain differs from the standard in any property it should be studied most carefully. This should be done also before reporting members of the paratyphoid-enteritidis group since strains of *B. coli* and of the so-called paracolon group may be agglutinated in sera prepared with certain of the pathogenic species. The similarity in biochemical and other properties and the close serological relationship of members of the paratyphoid-enteritidis group render the identification of individual species an arduous procedure. Furthermore, this is of little practical value because of the relatively low incidence in this country of infections with members of this group. The diagnostic significance of *B. alkalescens*, *B. dispar*, and *B. morgani* No. 1 has not been established but they are encountered with sufficient frequency to warrant recognition.

STANDARDIZATION OF ANTISERA

I. *Macroscopic slide agglutination tests*—Dilute the antiserum 1:25, 1:50, 1:100, 1:200, and higher if necessary, with 0.85 per cent salt solution. Perform macroscopic slide agglutination tests with a standard strain of the homologous species and with the other species of the bacilli inciting enteric disease. Test a similar series of dilutions of serum from a normal animal of the same species as that in which the antiserum was produced. If agglutination is obtained in the latter, procure a satisfactory strain of the species and repeat the tests. Select for use in routine tests the lowest dilution of antiserum in which definite agglutination occurs with the homologous but none with the heterologous species.

II. *Macroscopic tube agglutination tests*—Dilute the antiserum 1:100, 1:250, 1:500, 1:1,000, 1:2,000, and higher if necessary, with 0.85 per cent salt solution. Perform macroscopic tube agglutination tests with a standard strain of the homologous species and with the other species of the bacilli inciting enteric disease. Test a similar series of dilutions of serum from a normal animal of the same species as that in which the antiserum was produced. If agglutination is obtained in the latter, procure a satisfactory strain of the species and repeat the tests. Select for use in routine tests the two lowest dilutions of antiserum in which definite agglutination occurs with the homologous but none with the heterologous species.

III. *Absorption tests*—A serum dilution of 1:50 is usually found satisfactory for absorption tests. If this does not give satisfactory results, other dilutions may be tested.

Inoculate infusion agar in two pint Blake or other bottles of convenient size with the culture homologous to the serum being standardized, and incubate at from 35 to 37° C. for from 18 to 20 hours. Suspend the growth in a small amount of 0.85 per cent salt solution, and determine its turbidity in relation to that of barium-sulphate standard No. 3. Absorbing

TABLE II

Designation of Absorbing Suspensions	*Ratio to Turbidity of $BaSO_4$ Standard No. 3*	*Dilution Necessary to Give a Suspension Equal in Turbidity to $BaSO_4$ Standard No. 3*	
		Suspension Part	*Salt Solution Part*
No. 1	Same	1	0
No. 2	2 x	1	1
No. 3	10 x	1	9
No. 4	20 x	1	19
No. 5	50 x	1	49
No. 6	100 x	1	99
No. 7	200 x	1	199
No. 8	400 x	1	399

suspensions are designated as No. 1, No. 2, etc., in Table II.

The turbidity of absorbing suspensions varies with different species and different sera. Therefore, in initial standardization, test with three or four suspensions chosen arbitrarily. Combine equal parts of the suspensions and a dilution of the antiserum which is not more than one-eightieth of its titer.

Incubate the tests at approximately 50° C. for 3 hours, inverting the tubes occasionally to insure contact of microorganisms and serum. Leave the tubes in the refrigerator over night and then centrifugalize at high speed for 1 hour, or until the supernatant fluid is clear. Prepare dilutions of the supernatant fluid and combine 0.3 c.c. of each with 0.3 c.c. of a suspension in 0.85 per cent salt solution (comparable in turbidity to barium-sulphate standard No. 3) of a beef-infusion agar culture of the species homologous to the antiserum. Incubate the tests at from 35 to 37° C. for 2 hours and leave them in the cold room over night before reading, except in the case of *B. dysenteriae* Sonne and *B. alkalescens*. Incubate tests with these species at approximately 50° C. for from 18 to 20 hours, and record the reactions. Select as a standard for use in routine tests an absorbing suspension which completely removes the agglutinative properties through at least one-twentieth of the titer of the serum.

STANDARDIZATION AND TESTING OF DIFFERENTIAL MEDIA

Whenever a new lot of dye or indicator is purchased for use in any medium, test the medium with representative strains of the bacterial species inciting enteric disease as well as *B. coli*. Also, test the efficiency of each new lot of medium.

In the case of brilliant-green agar, the amounts of dye necessary must be determined for each lot of agar base. Prepare 6 plates each of agar containing 0.1, 0.2, 0.3, 0.4, and 0.5 per cent of a 0.1 per cent aqueous solution of brilliant-green dye. Inoculate portions of each set of plates with standard strains of *B. coli, B. typhosus, B. paratyphosus* A, *B. paratyphosus* B, and *B. dysenteriae* Shiga; and, if possible, fecal specimens from cases of typhoid fever or persons known to be carriers of *B. typhosus*. After incubation for from 18 to 20 hours at from 35 to 37° C., observe the growth and select for a "weak" dye agar, that dilution which best inhibits the growth of *B. coli* without materially affecting the growth of typhoid and paratyphoid bacilli. Choose for a "strong" dye agar that dilution which inhibits the growth of *B. coli* completely or nearly so, and the growth of *B. typhosus* and *B. paratyphosus* not more than 50 per cent.

Whenever a new lot of basic fuchsin is obtained, standardize it as follows.

for use in Endo's agar: To 100 c.c. amounts of agar base, add 0.05 c.c., 0.1 c.c., 0.2 c.c., and 0.3 c.c. of a saturated alcoholic solution and pour 6 plates from each. Inoculate portions of each set of plates with standard strains of *B. coli, B. typhosus, B. paratyphosus* A, *B. paratyphosus* B and *B. dysenteriae* Shiga and, if possible, fecal specimens from cases of typhoid fever or persons known to be carriers of *B. typhosus*. Examine the plates after incubation for from 18 to 20 hours at from 35 to 37° C. and select that amount of dye with which the sharpest differentiation of *B. coli* and the bacilli inciting enteric disease is obtained and which has no appreciable inhibitory action on the latter.

PREPARATION OF MEDIA AND REAGENTS

Details in regard to the preparation of media and reagents are given in the order in which they are mentioned in the preceding methods. Formulae for media in common use, such as, infusion and extract agar and broth, are not included. It is assumed that these would be available in any laboratory undertaking this type of work.

The source of dyes and chemicals which have been found satisfactory is indicated. Products which are shown to be equally reliable may be obtained from other manufacturers.

Hitchens Semifluid Agar [3]

Beef, ground	500 gm.
Distilled water	1 kg.
Peptone	10 gm.
Sodium chloride	5 gm.
Dextrose	1 gm.
Agar	1.5 gm.

Weigh the meat and add the required quantity of water. Stir thoroughly, and infuse over night in the cold room. Strain through cheesecloth, press off the juice from the meat with a meat press, and weigh. Heat gradually in a steam kettle or over a free flame, stirring occasionally, until the infusion is clear and almost colorless and the coagulum is brown. Strain through cheesecloth and filter through paper. Make up the weight to give 1 kg. of infusion for each 500 gm. of meat. Adjust the reaction to from pH 8.0 to 8.2. Add the peptone and the salt, and autoclave at 121° C. for from 30 to 40 minutes, depending on the bulk of the material. Make up the weight to that of infusion plus the other ingredients. Add the dextrose, dissolve, and filter through paper until clear.

Dissolve the agar in 50 c.c. of distilled water by heating in the autoclave at 121° C. for 30 minutes. Bring the filtered broth to the boiling point and add 40 c.c. of the melted aqueous agar per kg. Line the bottom of a Buchner funnel with two layers of filter paper cut to fit. Over these, place a thick pad of nonabsorbent cotton. Using a small amount of negative pressure and keeping the medium hot, filter it into a suction flask. Dispense in bottles or tubes in moderately tall columns and sterilize by steam at 121° C. for 20 minutes.

Conradi's Bile Medium (Modified) [4] *

Dehydrated ox bile	100 gm.
Glycerol	100 gm.
Peptone	20 gm.
Distilled water to make	1 kg.

* Slightly modified for purposes of convenience.

Combine the ingredients and dispense in from 8 to 10 c.c. amounts in wide-mouth tubes or jars. Sterilize by steam at 121° C. for 15 minutes.

Glycerol Sodium-chloride Solution [5]

Sodium chloride	6 gm.
Distilled water to make	1 kg.
Glycerol, T.P. (Schering-Kahlbaum, Berlin)	

Dissolve the salt in part of the water and make up to 1 kg. To 7 volumes of the 0.6 per cent salt solution, add 3 volumes of glycerol. Filter through paper.

Dispense in from 8 to 10 c.c. amounts in the tubes or jars used in the outfits to be distributed for the collection of specimens. Sterilize by steam at 121° C. for 20 minutes. After removing from the autoclave, allow the jars or tubes to cool to from 50 to 60° C., fasten the caps or stoppers securely, and leave standing over night in an inverted position. Discard leaky jars or tubes. Test the viability of the bacilli inciting enteric disease in each lot of glycerol solution prepared.

Eosin-methylene-blue Plating Medium [6]

Distilled water	1 kg.
Agar	20 gm.
Sodium chloride	5 gm.
Beef extract	3 gm.
Peptone	10 gm.

Dissolve the agar in about 90 per cent of the water by heating in an autoclave for 30 minutes at 121° C. Dissolve the peptone, salt, and extract in the remainder of the water by heating in a water-bath. Combine the two parts and make up the weight to that of all the ingredients. Adjust to from pH 7.0 to 7.2. Dispense in bottles of convenient size and sterilize by steam at 121° C. for from 30 to 40 minutes, depending on the volume. When plates are to be poured, melt the agar in steam at 100° C. To each 100 c.c. of medium add 5 c.c. of a sterile 10 per cent lactose solution, 1 c.c. of a 4 per cent aqueous solution of eosin, and 2 c.c. of a 0.5 per cent aqueous solution of methylene blue. Mix well before pouring into plates.

Eosin, 4 Per Cent, Aqueous Solution

Eosin (National Aniline)	40 gm.
Distilled water to make	1,000 c.c.

Dissolve the dye in part of the water and make up to volume. Store in a glass stoppered bottle.

Methylene Blue, 0.5 Per Cent, Aqueous Solution

Methylene blue (National Aniline)	5 gm.
Distilled water to make	1,000 c.c.

Dissolve the dye in part of the water and make up to volume. Store in a glass stoppered bottle.

Lactose Solution

Lactose	100 gm.
Distilled water to make	1 kg.

Dissolve the lactose in a small amount of distilled water and make up to volume. Filter through paper and dispense in convenient amounts in bottles or tubes. Sterilize by steam at 121° C. for 15 minutes.

Endo's Plating Medium—Robinson and Rettger's Modification [7, 8]

Distilled water	1 kg.
Agar	25 gm.
Peptone	10 gm.
Beef extract	5 gm.
Sodium carbonate (10 per cent solution)	10 c.c.
Lactose	10 gm.
Sodium bisulphite (10 per cent solution)	10 c.c.
Fuchsin (saturated alcoholic solution)—determined by standardization	

Add the water to the agar, reserving about 10 per cent or 100 gm. per kg. to dissolve the peptone and beef extract. Dissolve the agar by heating in an autoclave for 30 minutes at 121° C. Dissolve the peptone and extract by heating in a water-bath. Combine the two parts and make up the weight to that of all the ingredients. Filter through a thin layer of absorbent cotton. Add the solution of sodium carbonate. Check the reaction, which should be between pH 7.8 and 8.0. Heat in streaming steam at 100° C. for 10 minutes. Add the lactose and the fuchsin and mix well. Add sodium bisulphite and mix well again. Dispense in bottles in convenient amounts and sterilize by steam at from 115 to 116° C. for 20 minutes. Melt the agar and pour plates as needed.

Sodium Carbonate, 10 Per Cent Solution

Anhydrous sodium carbonate	100 gm.
Distilled water to make	1 l.

After dissolving the sodium carbonate in the water, standardize by titration with 1N hydrochloric acid.

Sodium Bisulphite, 10 Per Cent, Aqueous Solution

Sodium bisulphite	100 gm.
Distilled water to make...	1,000 c.c.

Dissolve the bisulphite in part of the water in a 1,000 c.c. volumetric flask. Make up to volume. Filter through paper and use immediately or store in a wide-mouth bottle under a ¾" layer of mineral oil. Fit the bottle with a siphon and when solution is required, dispense desired amount, using the siphon.

Fuchsin, Basic, Saturated Alcoholic Solution

Fuchsin, basic (National Aniline)	10 gm.
Alcohol, 95 per cent, to make	100 c.c.

Dissolve the dye in part of the alcohol and make up to volume. Shake well. Allow to stand over night, filter through paper and store in a glass stoppered bottle.

Brilliant-green Plating Medium [9]

Distilled water	1 kg.
Agar	15 gm.
Sodium chloride	5 gm.
Beef extract	3 gm.
Peptone	10 gm.
Andrade's indicator	30 c.c.

Dissolve the agar in about 90 per cent of the water by heating in an autoclave for 30 minutes at 121° C. Dissolve the peptone, salt, and extract in the remainder of the water by heating in a water-bath. Combine the two parts and make up the weight to that of all the ingredients. Filter through a thin layer of absorbent cotton.

Weigh the filtered agar and add 3 per cent of Andrade's indicator. Determine the reaction and, if it lies between pH 7.2 and 7.6, do not adjust. Otherwise, adjust to pH 7.6. Dispense five 100 c.c. amounts in bottles for purposes of standardization. Dispense the remainder in from 100 to 400 c.c. amounts in bottles of a suitable size. Sterilize by steam at 121° C. for from 30 to 40 minutes depending on the volume. As soon as the material is removed from the autoclave, add to each of the five 100 c.c. amounts of agar 5 c.c. of a sterile solution containing 2 per cent dextrose and 20 per cent lactose. To the first bottle add 0.1 c.c., to the second 0.2 c.c., to the third 0.3 c.c., to the fourth 0.4 c.c., and to the fifth 0.5 c.c. of a 0.1 per cent aqueous solution of brilliant-green dye. (These amounts may vary with different lots of brilliant-green dye.) From each bottle pour 6 plates to be employed for standardization.

When brilliant-green agar plates are to be prepared from a lot which has been standardized, melt the agar in steam at 100° C. and add a sufficient amount of a sterile solution containing 2 per cent dextrose and 20 per cent lactose to give 0.1 and 1 per cent respectively, of these cabohydrates. Add the required amounts of 0.1 per cent aqueous solution of brilliant green as determined by standardization.

Andrade's Indicator [10, 11]

Acid fuchsin (Coleman and Bell)	
Distilled water	1,000 c.c.
1N NaOH	100 c.c.

It is necessary to test each lot of fuchsin purchased. Make up a small amount of indicator using the same amount of fuchsin as was used with the preceding lot for the preparation of the indicator (from 1.5 to 5 gm. per l.). Incorporate this indicator in a very small amount of double-sugar medium and test it with cultures of the bacterial species inciting enteric disease. If the uninoculated medium of suitable reaction is decidedly pink when cold, less fuchsin should be used.

Lactose-dextrose Solution

Dextrose	20 gm.
Lactose	200 gm.
Distilled water to make...	1 kg.

Dissolve the carbohydrates in a small amount of distilled water and make up to volume. Filter through paper and dispense in convenient amounts in bottles or tubes. Sterilize by steam at 121° C. for 15 minutes.

Brilliant Green, 0.1 Per Cent, Aqueous Solution

Brilliant green (Coleman and Bell)	0.5 gm.
Distilled water to make. . .	500 c.c.

Dissolve the dye in part of the water and make up to volume. Store in a glass-stoppered bottle in the dark.

Russell's Double-sugar Medium[12]

Distilled water	1 kg.
Agar	15 gm.
Sodium chloride	5 gm.
Beef extract	3 gm.
Peptone	10 gm.
Andrade's indicator	30 c.c.
Lactose	10 gm.
Dextrose	0.5 gm.

Dissolve the agar in about 90 per cent of the water by heating in an autoclave for 30 minutes at 121° C. Dissolve the peptone, salt, lactose, dextrose, and extract in the remainder of the water by heating in a water-bath. Combine the two parts and make up the weight to that of all the ingredients. Filter through a thin layer of absorbent cotton.

Weigh the filtered agar and add 3 per cent of Andrade's indicator. Determine the reaction and, if it lies between pH 7.2 and 7.6, do not adjust. Otherwise adjust to pH 7.6. Dispense in tubes and after sterilization by steam at 121° C. for 12 minutes, cool in a slanted position so that the agar will form a butt about 1″ deep and a slant from 1.5 to 2″ long.

Peptone Water with Carbohydrate[13]

(For determination of acid production)

Distilled water	1 kg.
Peptone	10 gm.
Sodium chloride	5 gm.
Andrade's indicator	10 c.c.

Add the peptone and salt to the water, and dissolve, warming if necessary. Filter through paper. Add the indicator and adjust to from pH 7.4 to 7.5. Dispense in convenient amounts in bottles and sterilize by steam at 121° C. for 20 minutes.

Add sterile solutions of carbohydrates to give 1 per cent and dispense in from 1 to 2 c.c. amounts in small tubes, using precautions to avoid contamination. Solutions of carbohydrates sterilized by filtration should be employed, except in the case of those which are relatively stable at high temperatures. Seal with paraffin to prevent evaporation.

Beef-extract Broth with Carbohydrate[14]

(For determination of gas production)

Distilled water	1 kg.
Beef extract	3 gm.
Peptone	5 gm.
Carbohydrate	5 gm.

To the required quantity of water add the extract and peptone. Dissolve by heating over a free flame, stirring frequently. Adjust to pH 7.0. Boil for about 5 minutes. Make up lost weight. Add the sugar, dissolve, and filter through paper until clear. Dispense in Durham fermentation tubes with outer tube 150 by 19 mm. and inner tube 75 by 11 mm. in size. Fill a small amount of broth (about 1.5 cm. depth) into the large tube, fill the small tube completely and invert in the large tube. Sterilize by steam at 121° C. for 12 minutes.

Dunham's Peptone Solution (Modified)[15]

(For determination of indol production)

Distilled water	1 kg.
Peptone (Parke-Davis) . . .	10 gm.
Potassium nitrate C.P.	0.1 gm.

Dissolve the peptone in the water, warming if necessary, and adjust to pH 7.0. Add the nitrate, and filter through paper. Dispense in from 5 to 6 c.c. amounts in tubes and sterilize by steam at 121° C. for 15 minutes.

Parke-Davis peptone, or some other brand known to be satisfactory for indol production, must be used.

Ehrlich's Reagent

(For determination of indol production)

Paradimethylamino benzaldehyde (Pfanstiehl) . . .	1 gm.
Absolute alcohol	95 c.c.
Concentrated hydrochloric acid	20 c.c.

Store in a glass-stoppered bottle.

This reagent should be used within 2 months after preparation.

Litmus Milk

Milk, certified or Grade A, unpasteurized.	1 quart
Litmus solution, 10 per cent, aqueous	2 per cent by volume

Pour the milk into a separatory funnel and place in the refrigerator over night to allow the cream to rise. Draw off the fat-free milk and add the required volume of litmus solution. If necessary, adjust the reaction to neutral to the indicator. Dispense in from 5 to 6 c.c. amounts in tubes and sterilize by steam at 100° C. for 20 minutes on 3 successive days.

Litmus Solution

Purified litmus	10 gm.
Distilled water to make. .	100 c.c.

Grind the litmus in a mortar. Transfer to a 100 c.c. volumetric flask, add about one-half of the water, and shake vigorously. Allow to stand and shake again. Repeat. Finally add sufficient water to make up to volume. Allow to settle over night, decant the clear solution, and centrifugalize until clear. Add 0.5 per cent chloroform and store in a glass-stoppered bottle in a refrigerator.

Purified litmus may be purchased or may be prepared [16] as follows:

Commercial litmus	20 gm.
Alcohol, 85 per cent.	500 c.c.
(445 c.c. of 95 per cent alcohol diluted to 500 c.c.)	

Powder the litmus in a mortar. Transfer to an evaporating dish and add 100 c.c. of alcohol which has been heated to boiling on a steam bath. Place the evaporating dish in the steam bath and digest with frequent stirring for 15 minutes. Centrifugalize and discard the alcoholic supernatant solution. Extract the precipitate in this manner 5 times. Transfer the extracted litmus to a shallow dish and dry in a vacuum desiccator over concentrated sulphuric acid.

Tentative Methods for the Isolation and Identification of Hemolytic Streptococci*

As aids to diagnosis, laboratory methods depend upon definite knowledge of the etiological relationship of a microörganism to a disease process. That hemolytic streptococci incite many quite different and characteristic infectious processes is well established, but no specific relationship of any of the various streptoccoci to a particular disease has as yet secured general acceptance. Knowledge of the biological characters, however, has advanced steadily and to a stage of real, though limited, usefulness for the isolation and identification of hemolytic streptococci. Certain difficulties arise in the practical

* Report of the Referee on Recognition and Significance of Hemolytic Streptococci in Infectious Diseases for the Standard Methods Committee on Diagnostic Procedures and Reagents.

application of this knowledge because of the variety of procedures and the lack of essential information in the literature. Therefore, as a preliminary step in the standardization of methods, tentative procedures which have proved practical in actual use for the preparation and examination of specimens for hemolytic streptococci and for their identification have been formulated; they are submitted for study and criticism.

GENERAL DIRECTIONS

I. PREPARATION OF SPECIMEN FOR EXAMINATION

A. Specimens are collected in sterile glass containers, stoppered or sealed to prevent leakage and contamination. Each specimen container bears a label on which is written the patient's name and, if sent to the laboratory by mail, it is packed in such a way as to comply with the postal regulations. Specimens of milk are kept iced until examined. If this is impossible, one volume of glycerol [1] — Schering Kahlbaum — is mixed thoroughly with two volumes of milk as soon as the sample is taken.

B. Each specimen is accompanied by a history slip on which the following data are recorded: kind of specimen and date of collection, identification and pertinent clinical history of the patient or subject, and the name and address of the physician.

C. Specimens are opened and numbered one at a time in order to avoid the possibility of interchanging them. This number is recorded on the specimen label and on the history slip. The records of all examinations made of the specimen are marked with this number.

II. APPARATUS AND TECHNIC FOR EXAMINATION

A. All glassware, solutions, and media are sterile and handled with the usual precautions to prevent contamination.

B. Incubators are maintained at a temperature of from 34 to 36° C. and are equipped with thermometers which register maximum and minimum temperatures.

C. Solid media are inoculated with a wire loop. Plate cultures are made by streaking one loopful (1 mm.) of material in parallel rows with particular care to avoid breaking the surface of the medium. Liquid media are inoculated by adding with a pipette suitable volumes of 18 hour broth culture.

D. With the following exceptions, inoculated media are incubated under aerobic conditions: blood-agar plates used for isolation and fishings from these plates to broth of strains which fail to grow aerobically.

E. Preparations for microscopic examination are made by spreading a loopful of material evenly on a glass slide and are stained by Gram's method. Films of *B. coli* and of *Staphylococcus aureus* are placed on each slide as controls of the staining procedure. When pus cells are present, the staining reactions of their nuclei serve as an excellent control.

F. Seed cultures for the inoculation of the various test media are incubated for 18 hours and examined microscopically before use, and are streaked on blood agar after use to assure their purity. If any evidence of contamination is noted, the differential tests are repeated with cultures freed from contaminants by plating and fishing.

ISOLATION

I. MEDIA *

A. Blood agar [2] for plates and slants: Preparation—

Beef heart, ground........	1 kg.
Distilled water	2 kg.
Agar, shredded No. 40, A. H. Thomas Co.	40 gm.
Sodium chloride, C.P.....	10 gm.
Peptone, "Difco" Bacto...	10 gm.

* The preparation of the different media is still under investigation, with a view to simplifying the procedures.

Mix the meat and 1 kg. of water thoroughly and infuse over night at 5° C. Skim the fat and heat the infusion to 45° C., hold at between 45 and 50° C. for 1 hour, and then boil for ½ hour. Stir frequently throughout the heating process. Remove the coarse particles by straining through a colander, and filter through glass wool which has been washed thoroughly in distilled water. Add distilled water to make 1 kg. and adjust the infusion to pH 7.4. Boil for 5 minutes and filter again through glass wool and make up any loss in weight with distilled water.

Dissolve the agar and sodium chloride in 1 kg. of water by heating in an autoclave at 121° C. for 30 minutes. Mix equal parts of this solution and the infusion with the peptone and adjust the reaction to pH 7.4 if necessary. Filter through glass wool, dispense the medium in suitable quantities, and sterilize by steam at 121° C. for 30 minutes.

Melt 900 c.c. of the beef-heart-infusion agar, cool to 45° C., and add 50 c.c. of sterile defibrinated horse, rabbit, or human blood. Dispense in tubes or Petri plates. After solidification, leave at room temperature for 48 hours, and examine for contamination. Store at 5° C.

Testing—Test each lot of medium by inoculating plates with several strains of streptococci of known hemolytic activity; include in this test at least one strain, the hemolytic activity of which is inhibited by the presence of small quantities of dextrose in the medium. Incubate under aerobic conditions, and examine for hemolysis after 24 hours. Do not use the medium unless all control strains induce distinct hemolysis.

B. Beef-infusion agar, 0.12 per cent,[3] *for blood cultures:*

Beef, ground	500 gm.
Distilled water	1 kg.
Peptone, "Difco" Bacto..	10 gm.
Sodium chloride, C.P......	5 gm.
Dextrose, anhydrous C.P., Merck	1 gm.
Agar, 3 per cent aqueous...	40 c.c.

Mix the meat and water thoroughly and infuse over night at 5° C. Strain through cheesecloth and press the juice from the meat in a meat press. Heat to 45° C. in a water-bath and hold at that temperature for 1 hour. Boil for 50 minutes, stirring occasionally, and filter through glass wool which has been washed thoroughly in distilled water. Add distilled water to bring weight to that of the water added originally, and adjust to from pH 8.0 to 8.2. Dissolve the peptone, salt, and dextrose in the infusion. Filter through glass wool until clear. Warm the filtrate, add the melted agar, and filter through glass wool if necessary. Dispense and sterilize by steam at 121° C. for 30 minutes.

C. Beef-infusion broth[4]*:*

Beef, ground	500 gm.
Distilled water	1 kg.
Peptone, "Difco" Bacto...	10 gm.
Sodium chloride, C.P.......	5 gm.

Mix the meat thoroughly with approximately 90 per cent of the water, reserving the remainder to dissolve the peptone and salt. Infuse over night at 5° C., strain the infusion through cheesecloth, and press the juice from the meat with a meat press. Dissolve the peptone and salt in the water by heating in a water-bath, and add to the infusion. Adjust the reaction to neutral to phenolphthalein. Boil for 30 minutes. Check the reaction and, if it is more acid than pH 8.0, adjust and boil for 3 minutes. Filter through paper and make up weight with distilled water to the total of all ingredients, excluding the meat. Dispense and sterilize by steam at 100° C. for 40 minutes on 3 successive days. Incubate for 48 hours, and examine for contamination before use.

II. PLATING OF SPECIMEN

Plate each specimen in duplicate on blood-agar medium (see Isolation I A)

by streaking the surface of each plate with one loopful of material. Incubate one plate under anaerobic conditions in a hydrogen jar [5] containing as a control a tube of methylene-blue indicator* and examine for growth after 48 hours; incubate the other under partial carbon-dioxide tension † and examine after 24 hours; if no growth of hemolytic streptococci is present, examine again after 48 hours.

A. Blood:

Keidel tube—Open the tube in a flame and with a bulb Pasteur pipette or a 20 c.c. syringe (needle, 17 gauge, 1½"), transfer approximately 15 c.c. of the contents to a test tube. From this material make a slide preparation; transfer from 3 to 5 c.c. to each of two 100 c.c. bottles containing 45 c.c. of 0.12 per cent beef-infusion agar which has been warmed to 37° C., and streak a loopful on each of two blood-agar plates. If no growth is present on these plates after incubation, make stained preparations and inoculate plates from the 0.12 per cent beef-infusion-agar cultures after 2, 7, and 14 days' incubation.

If the patient is available to the laboratory, inoculate bottles of 0.12 per cent beef-infusion-agar medium with the freshly drawn blood and proceed as indicated above.

Clotted blood—Pipette the serum from the clot without centrifugalization and place the clot in a 200 c.c. bottle containing 110 c.c. of 0.12 per cent beef-infusion agar which has been warmed to 37° C., and incubate. Make a slide preparation from and plate on blood agar the material left in the tube after the removal of the clot. If no growth is present on these plates after incubation, make stained preparations and inoculate plates from the 0.12 per cent beef-infusion-agar culture after 2, 7, and 14 days' incubation.

B. Nose and throat cultures:

Loeffler's coagulated serum medium—If the specimen consists of an inoculated slant of Loeffler's coagulated serum medium, incubate for from 18 to 24 hours. Make a slide preparation by passing a loop lightly over the entire surface of the medium and spreading the material evenly in a drop of water on a slide. Suspend a representative loopful of culture in 2 c.c. of 0.85 per cent salt solution and plate on blood agar.

If the swab with which the culture was taken is returned with Loeffler culture, treat as described below.

Swab—Wash the swab in 2 c.c. of 0.85 per cent salt solution, and streak both the moist swab and the washings on one half of each plate. Make stained preparations from both the swab and its washings.

If the patient is available to the laboratory, inoculate the blood-agar plates with the swab at the bedside. Return plates to the laboratory for incubation and examination. Also return the swab and, if no growth of hemolytic streptococci occurs on the plates inoculated at the bedside, examine the swabs as indicated above.

C. Purulent discharges:

Tube specimen—Make a stained preparation and plate on blood agar. If the examination of stained preparation indicates the presence of a large number of microörganisms, dilute a portion of the material with 0.85 per cent salt solution before plating.

Swab—Proceed as in the examination of swabs—nose and throat cultures.

D. Spinal fluid:

---

* Methylene-blue indicator: Mix in a test tube equal parts of N/160 sodium hydroxide, 0.015 per cent aqueous methylene blue, and 6 per cent sterile aqueous solution of dextrose. Boil until the methylene blue is reduced, and place in the hydrogen jar immediately before it is sealed for the removal of the oxygen. The indicator remains colorless as long as anaerobic conditions are maintained.

† Place the inoculated plates in a 2½ liter museum jar or other container of similar volume which can be sealed tightly. Put a tube containing approximately 0.6 gm. of sodium carbonate in the jar in an upright position and with a pipette add 10 c.c. of 10 per cent sulphuric acid. Seal the jar as soon as the reaction begins to subside.[6]

Centrifugalize at approximately 2,000 r.p.m. for ½ hour, remove the supernatant fluid, and make a stained preparation from the sediment. Draw the remainder of the sediment into a fine capillary pipette, place 1 drop on each plate, and streak with a wire loop. If microscopic examination of the stained preparation indicates the presence of Gram-positive cocci, inoculate also a tube of beef-infusion broth (see Isolation I C).

E. Milk:

Centrifugalize at approximately 2,000 r.p.m. for ½ hour to separate the cream. Draw off the skim milk with a capillary pipette, and discard. Make a stained preparation and plate on blood agar the mixed cream and sediment.

If haste is not required, store the milk specimen at 5° C. until the cream has separated. Make a stained preparation and plate the gravity cream.

III. FISHING COLONIES

Examine the plates thoroughly after incubation for isolated hemolytic colonies of characteristic appearance. Fish several colonies, transferring part of the growth from each colony to a blood-agar slant and a tube of beef-infusion broth* (see Isolation I C). If hemolytic colonies are present, but are overgrown, suspend some of the growth from these areas in 0.85 per cent salt solution, and replate. If the growth is heavy—few or no isolated colonies—dilute a portion of the specimen with 0.85 per cent salt solution and replate.

Incubate fishings to blood-agar slants until growth is obtained, usually 24 hours, examine the growth macroscopically for homogeneity and hemolytic activity, and store at 5° C. for further study if necessary.

After incubation, examine fishings to broth microscopically for the presence of Gram-positive cocci which form chains. Plate on blood agar and incubate under aerobic conditions. Examine the growth on the plates for homogeneity and hemolytic activity.

IDENTIFICATION

The extent to which the procedures for identification and differentiation are carried is determined by the type of specimen and the purpose of the examination. For microörganisms from specimens of blood and spinal fluid and, in many instances, purulent discharges, a study of the morphology and hemolytic activity alone suffices to establish the etiological relationship. With strains from milk and from nose and throat cultures, particularly when they are examined in connection with the investigation of outbreaks of streptococcus infections, however, additional data are essential.

The presence in the normal nose and throat, and in the udders of cows, of hemolytic streptococci, usually considered of little importance as incitants of infectious disease in man, has necessitated the formulation of procedures by which the common human pathogens may be differentiated. In general, these strains are hemolytic not only when grown on blood agar but also when examined by means of the tube test. They also produce a pH of 4.6 or above in 1 per cent dextrose broth, ferment trehalose, fail to ferment sorbitol, or to hydrolyze sodium hippurate, and, according to the results of precipitation tests, are members of Group A described by Lancefield.

I. TUBE TEST FOR HEMOLYSIS [7, 8]

Add 0.5 c.c. of a 15 hour beef-infusion broth (see Isolation I C) culture to 0.5 c.c. of 5 per cent horse, rabbit, or human red-blood cells washed 3 times in 0.85 per cent salt solution. Mix

---

* If a strain is encountered fishings of which fail to grow in this medium, add to the broth approximately 10 per cent of normal serum or 5 per cent of defibrinated blood.

thoroughly and incubate in a water-bath for 2 hours at 37° C. Examine for hemolysis after ½, 1, and 2 hours. For purposes of control, include two tubes, one containing 0.5 c.c. of uninoculated broth mixed with 0.5 c.c. of cells, and the other containing 0.5 c.c. of culture of a known hemolytic strain and 0.5 c.c. of cells. At the end of the 2 hour incubation period, centrifugalize any tubes in which hemolysis appears incomplete or is absent, and compare them with the uninoculated broth control.

II. DIFFERENTIAL TESTS FOR THE IDENTIFICATION OF STRAINS COMMONLY ENCOUNTERED IN HUMAN INFECTIONS

A. Final hydrogen-ion concentration [9, 10]:

Medium: Dextrose beef-infusion broth—

Beef, ground	500 gm.
Distilled water	1 kg.
Peptone, "Difco" Proteose	20 gm.
Sodium chloride, C.P.	5 gm.
Dextrose, anhydrous C.P., Merck, 20 per cent solution	50 c.c.

Mix the meat and water thoroughly and infuse over night at 5° C. Strain through cheesecloth and press the juice from the meat in a meat press. Boil for 30 minutes, stirring occasionally. Strain through cheesecloth and filter through paper. Dissolve the peptone and salt in the filtrate and make up weight with distilled water to the sum of all the ingredients, excluding the meat. Adjust the reaction to pH 8.2 and heat at 121° C. for from 30 to 40 minutes, depending on the bulk of the material. Make up weight, and check the reaction. If it is more acid than pH 8.2, readjust and boil for 3 minutes. Filter through paper until clear and sterilize by steam at 121° C. for 20 minutes.

Add the heat-sterilized 20 per cent dextrose solution to the medium aseptically and dispense in 5 c.c. amounts in 125-by-13-mm. tubes. Incubate the finished medium for 2 days and examine for contamination.

Procedure—Inoculate a tube of dextrose beef-infusion broth with 0.2 c.c. of broth culture, and incubate for 96 hours. Determine the hydrogen-ion concentration colorimetrically.

Colorimetric determination of hydrogen-ion concentration—Pipette 2 c.c. of freshly boiled and cooled distilled water and 1 c.c. of the supernatant fluid from dextrose-broth culture into each of two clear hard-glass tubes, 75-by-11-mm. To one of these add 0.1 c.c. of methyl red [11, 12] * or other indicator of suitable range, and mix thoroughly the contents of both tubes. In a comparator block superimpose the tube containing the diluted culture and indicator upon a tube of distilled water; superimpose the other tube upon a color standard prepared by adding 1 c.c. of standard buffer solution [13, 14] of suitable hydrogen-ion concentration and 0.1 c.c. of indicator to 2 c.c. of distilled water. Record as the hydrogen-ion concentration of the culture that of the standard which it most nearly matches in color. (Because of the instability of methyl-red indicator, fresh "standards" should be prepared daily.)

B. Hydrolysis of sodium hippurate [15]:

Medium: Sodium-hippurate pepsin broth—[16]

Distilled water	1 kg.
Peptone, Parke-Davis Bacteriologic	10 gm.
Pepsin, U.S.P., Eimer and Amend	5 gm.
Calcium chloride, C.P.	0.03 gm.
Ferric chloride, C.P., Baker, 1 per cent solution	1 drop
Sodium hippurate, C.P., Eimer and Amend	5 gm.

Dissolve all the ingredients except the sodium hippurate in the water, divide in two equal parts, and adjust one to

* Methyl red is prepared according to the procedure given in the reference to Standard Methods, except that 60 per cent alcohol is used in place of distilled water for the final dilution.

pH 7.1. To the other part—500 gm.—of medium, add the sodium hippurate and adjust to pH 7.1. Boil both for 2 minutes, add distilled water to compensate for loss in weight, and filter through paper. Dispense in 5 c.c. amounts in 125-by-13-mm. tubes and sterilize by steam at 121° C. for 20 minutes.

Procedure—Inoculate a tube of sodium-hippurate pepsin broth with 0.2 c.c. of broth culture and incubate for 48 hours, or longer if growth is poor. Inoculate and incubate similarly a tube of the same medium to which no sodium hippurate has been added. To 2 c.c. of these cultures add 0.5 c.c. of 12 per cent ferric-chloride solution, prepared by dissolving the salt in distilled water containing 2 c.c. of concentrated hydrochloric acid per liter. Mix thoroughly and let stand for from 5 to 10 minutes before recording the presence or absence of hydrolysis—presence indicated by the formation of a heavy precipitate. With each series of cultures tested, include as controls two strains, one of which does and the other of which does not hydrolyze sodium hippurate.

C. Fermentation of trehalose and sorbitol [17, 18]*:*

Medium: 3 per cent chlor-phenol-red beef-infusion broth—

Beef-infusion broth (see Identification IIA, *without* dextrose)	100 c.c.
Chlor-phenol-red [11, 12]	3 c.c.
Trehalose, "Difco" standardized, 10 per cent solution, sterilized by filtration	10 c.c.
or	
d-Sorbitol, "Difco" standardized, 10 per cent solution, sterilized by heat	10 c.c.

Add the indicator to the sterile broth and heat by steam at 100° C. for 20 minutes. Cool and add either trehalose or sorbitol aseptically and dispense in approximately 2 c.c. amounts in 75-by-11-mm. tubes. Incubate for 48 hours, and examine for contamination. For control purposes dispense similarly an equal number of tubes of the medium containing the indicator but no added carbohydrate.

Procedure—Inoculate a tube of 3 per cent chlor-phenol-red beef-infusion broth containing each of the test substances with 0.1 c.c. of culture. As a control on the amount of natural sugar in the medium, inoculate similarly a tube of the medium to which no carbohydrate has been added. Incubate for 1 week and record the presence or absence of fermentation after 1, 2, and 7 days.

D. Group-precipitation test [19]*:*

1. Extracts of strains

Medium: Infusion-free peptone broth —[20, 21]

Sodium chloride, C.P.	5 gm.
Dipotassium phosphate, C.P.	1 gm.
Monopotassium phosphate, C.P.	1 gm.
Peptone, Parke-Davis Bacteriologic	20 gm.
Cane sugar	2 gm.
Distilled water to make	1 kg.

Dissolve the sodium chloride in part of the water, add peptone, and heat slightly to dissolve. Dissolve the potassium salts separately in small quantities of water, and add to the peptone-salt solution. Add water to make 1 kg., and adjust to pH 7.8. Heat at 121° C. for 40 minutes, add cane sugar, and make up with water any loss in weight. Filter through paper until clear, dispense in 450 c.c. amounts in 1 liter Erlenmeyer flasks, and sterilize by steam at 121° C. for 30 minutes.

Procedure — Inoculate infusion-free peptone broth* with approximately 8 c.c. of broth culture, and incubate for 48 hours. Examine a stained preparation and streak on a blood-agar plate. If microscopic examination reveals no evidence of contamination, separate the bacterial cells by centrifugalization, and discard the supernatant broth. Wash

---

* For certain strains which fail to grow in this medium, beef-infusion broth (see Identification IIA, containing 0.02 per cent dextrose) is used.

the cells by suspending them in 25 c.c. of 0.85 per cent salt solution and centrifugalize. After discarding the salt-solution washings, mix with the sediment 4.5 c.c. of 0.85 per cent salt solution containing sufficient N/1 hydrochloric acid to make a final concentration of N/20 hydrochloric acid. Heat in a boiling water-bath for 20 minutes. Cool under running water, centrifugalize, pipette off the supernatant fluid, and discard the sediment. Adjust the supernatant fluid with N/1 sodium hydroxide to from pH 7.0 to 7.2 by the spot-plate method.* Centrifugalize and pipette off the clear supernatant fluid for use in the test if a pure culture of hemolytic streptococci grows on the blood-agar plate inoculated with the infusion-free peptone broth culture.

2. *Immune sera*

Preparation of formalin-treated culture—Inoculate a suitable volume, from 50 to 100 c.c., of broth (see Identification II A, containing 0.02 per cent dextrose) and incubate for 18 hours. Examine a stained preparation, and streak on a blood-agar plate. If no evidence of contamination is obtained from the examination of the stained preparation, separate the bacterial cells from the broth by centrifugalization and resuspend in one-twentieth the volume of 0.85 per cent salt solution containing 0.25 per cent formalin. Store at 5° C. for 48 hours and, if no contaminants are noted in the plate culture, plate the formalinized suspension on blood agar. Retest after further storage if growth occurs. Dilute formalin-treated culture with 0.85 per cent salt solution to the original volume of the culture immediately before each inoculation.

* Place one loopful of phenol red 11, 12 in each of several depressions in a porcelain reaction plate. With a 0.2 c.c. pipette add 0.04 c.c. of the adjusted extract, mix thoroughly, and compare with the color standards prepared by mixing similar amounts of indicator and standard buffer solutions of pH 7.0 and 7.2 respectively. Add N/1 sodium hydroxide or N/1 hydrochloric acid as indicated. (From 0.12 to 0.14 c.c. of N/1 sodium hydroxide is usually required to adjust 4.5 c.c. of the extract.)

Immunization of rabbits—Inoculate rabbits weighing approximately 2,000 gm. with formalin-treated cultures of strains representative of the various groups. Inject intravenously 1 c.c. of culture daily on 6 successive days, and take trial bleedings 5 days after the 6th inoculation. Test sera with extracts of homologous and heterologous strains which represent types belonging to the same group. Administer additional series of injections as indicated from the results of tests of trial bleedings, and bleed out animals from the 5th to the 7th day following the last injection.

3. *Precipitation test*

Pipette 0.1 c.c. of undiluted serum into 100-by-8-mm. tubes and add without mixing an equal volume of the extract* to be tested. Include as controls tubes containing similar volumes of each extract and 0.85 per cent salt solution, of 0.85 per cent salt solution and each serum, and of homologous extract and serum. Record the presence of ring formation after the test has stood for 10 minutes at room temperature or in a water-bath at 37° C. If no ring formation occurs with any of the group sera, incubate for 2 hours in a water-bath at 37° C. and store over night at 5° C. before recording the final results.

Reporting Results

A written report on the examination of each specimen is sent to the physician who submitted the specimen. The presence of hemolytic streptococci is reported as soon as the microörganisms are isolated in pure culture. In those instances in which the differential tests are performed, this report is followed by one recording the results of further procedures for identification.

Report " Hemolytic streptococci were found " or " were not found," depending upon whether or not Gram-positive cocci

* Depending upon the potency of the immune sera, it may be necessary to increase or decrease the amount of antigen used in the test.

which form chains and hemolyze red-blood cells are isolated.

Report "Hemolytic streptococci were found which belong to the group commonly encountered in human infections" when hemolytic streptococci are isolated which have a final pH of 4.6 or higher in 1 per cent dextrose broth, ferment trehalose, fail to ferment sorbitol, and to hydrolyze sodium hippurate and which, according to precipitation tests, are members of Group A.

Report "Hemolytic streptococci were found which differ in certain of their serological properties from those commonly encountered in human infections" when hemolytic streptococci are isolated which do not belong to Group A according to precipitation tests. Such strains may be similar to or differ from the common human pathogens in biochemical properties.

SPECIAL TESTS

In the investigation of outbreaks of hemolytic streptococcus infections, especially those in which epidemiological data point to a carrier as the source of the incitant, differentiation of members of the group commonly encountered in human infections is occasionally essential. Until the practical value of various serological procedures for the typing of strains [22, 23] is established, the demonstration of differences in their biochemical and toxigenic properties may yield helpful information. Furthermore, the study of the toxigenic characters may prove of very practical value, not only in the control of epidemics but also in the treatment of cases, if and when the hemolytic streptococci are classified according to toxin group and thus in relation to the antitoxic or antibacterial sera, rather than by disease entity.

I. FERMENTATION OF LACTOSE, MANNITOL, AND SALICIN [24]

Medium: 3 per cent chlor-phenol-red beef-infusion broth—

Beef-infusion broth *without* dextrose	100 c.c.
Chlor-phenol-red [11, 12]	3 c.c.
Lactose, "Difco" standardized, 10 per cent solution sterilized by filtration	10 c.c.
Mannitol, Merck, 10 per cent solution sterilized by heat	10 c.c.
Salicin, U.S.P., Merck, 10 per cent solution sterilized by filtration	10 c.c.

Prepare the medium as described under Identification IIC, substituting lactose, mannitol, or salicin for the trehalose or sorbitol.

Procedure (see Identification II C)—Test for toxin production strains which have not been differentiated by this test.

II. TOXIGENIC PROPERTIES [25, 26, 27]

A. Preparation of filtrates:

Medium: Beef-infusion broth (see Identification II A) containing 0.02 per cent dextrose.

Procedure—Inoculate a 50 c.c. Erlenmeyer flask containing 20 c.c. of broth and incubate for 48 hours. If the examination of a stained preparation reveals characteristic morphology, plate on blood agar, add 0.5 per cent phenol—C. P., Baker—and sterilize by passage through a Seitz or Berkefeld filter. Store at 5° C. If no contaminants are noted on the blood-agar plate, test the filtrate by the intracutaneous inoculation of susceptible rabbits.

B. Test for toxin production:

Animal—Select white-skinned rabbits—weight, at least 3,000 gm.; age, 1 year or older—and remove the hair from a small area on one flank with electric clippers. Dilute the standard toxin with 0.85 per cent salt solution so that 0.1 c.c. of the diluted material contains 5 skin test doses of toxin. Heat a portion of the diluted toxin for 2 hours in a boiling water-bath and inject 0.1 c.c. of the heated and of the unheated material intracutaneously in the depilated area on the rabbit. Examine the rabbit

24 hours after inoculation and record the size of the reaction and the degree of redness and swelling at the site of each injection. For the determination of toxigenic activity, it is necessary to use rabbits in which 5 skin test doses of the standard toxin induce definite reactions of approximately 2 cm. in diameter and in which the heated toxin fails to react.

Procedure—Make a 1:100 dilution in 0.85 per cent salt solution of the filtrate of the strain to be tested and heat a portion of the dilution for 2 hours in a boiling water-bath. With a 1 c.c. tuberculin syringe (needle, 26 gauge, ⅜"), inject 0.1 c.c. of the heated filtrate, followed by 0.1 c.c. of the unheated material, intracutaneously in separate areas of the depilated back or sides of a susceptible rabbit. On the same animal inject 5 skin test doses of standard toxin, heated and unheated. After 24 hours, record the size of the reaction and the degree of redness and swelling at the site of each inoculation. If 0.001 c.c. of unheated filtrate (0.1 c.c. of 1:100 dilution) induces a reaction measuring 1 cm. or more in diameter and the heated filtrate fails to react, consider the strain toxigenic.

If the strains cannot be differentiated by their ability or failure to produce toxin, test the filtrates of the toxigenic strains for neutralization by antistreptococcus serum.

C. *Test for neutralization by antistreptococcus serum:*

Prepare dilutions of standard toxin in 0.85 per cent salt solution so that 5 skin test doses are contained in 0.1 and 0.05 c.c. respectively. Divide the first dilution in two parts and heat one for 2 hours in a boiling water-bath. Add the second dilution to the standard antistreptococcus serum so diluted with physiological salt solution that 0.05 c.c. contains sufficient serum to neutralize from 5 to 10 skin test doses of homologous toxin.

Make dilutions of 1:100 and 1:50 of the toxin to be tested and heat a portion of the 1:100 dilution for 2 hours in a boiling water-bath. Add the 1:50 dilution to an equal volume of serum diluted as for the control toxin-serum mixture.

After the toxin-serum mixtures have been allowed to stand at least ½ hour at room temperature, inject 0.1 c.c. of each intracutaneously in a susceptible rabbit. Inoculate the same animal with 0.1 c.c. amounts of heated and unheated toxins and of serum alone, so diluted that 0.1 c.c. contains sufficient serum to neutralize from 5 to 10 skin test doses of homologous toxin. Use a different 1 c.c. tuberculin syringe (needle, 26 gauge, ⅜") for the injection of the serum control, for the toxin-serum mixtures, and for the heated and unheated toxins. After 24 and 48 hours record the size of the reaction and the degree of redness and swelling at the site of each inoculation.

Consider the test toxin neutralized by the antistreptococcus serum under the following conditions: no reactions at the site of the injections of heated toxins, of serum alone, and of mixtures of serum and test and standard toxins; reactions more than 1 cm. in diameter induced by both test and standard toxins.

For further information concerning the identification and differentiation of the streptococcus toxins, consult references 25, 26, and 27 in the bibliography.

Tentative Methods for the Diagnosis of Meningococcus Meningitis and Identification of the Meningococcus*

DEFINITION

It is necessary, first of all, to define what is meant by a meningococcus in order to establish definite criteria for its identification. Such a definition should include only such characteristics as are essential for identification. Reducing these to their very lowest terms we may, for practical purposes, begin with the following:

> The meningococcus is a Gram-negative coccus, usually occurring in pairs with flattened adjacent sides, which ferments dextrose and maltose with the production of acid.

The cocci may occur singly and sometimes in groups, and the individual cells may vary greatly in size and in intensity of staining, though they are always Gram-negative. Strains that fail to ferment maltose or dextrose, or both of these sugars, may be encountered. Such strains usually acquire this property sooner or later, though it may be lacking at a time when it is desired to make a diagnosis of meningococcus infection. In our recent studies of 610 strains of meningococci we have found no strain that has failed to ferment these two sugars at some time during our investigations.

Opinions as to the adequacy of the above brief definition will not be unanimous. Four other characteristics would be included by many workers with meningococci:

> Characteristic colony formation, lack of pigment production, growth only at incubator temperatures, and agglutinability by polyvalent anti-meningococcus serum.

As a rule the smooth translucent colonies of the meningococcus are quite characteristic, but occasional strains of true meningococci are found that immediately after isolation may be as large as a dime, very convex, or even opaque.

Most are agreed that meningococci never produce yellow pigment. The only dissenting voices are of those who consider *Neisseria flavescens* [1] to be a form of meningococcus,[2, 3] though both culturally and serologically *N. flavescens* seems quite distinct.

That meningococci grow only at incubator temperature is, as a rule, a safe generalization to make. We have

* Report of the Referee on the Diagnosis of Meningococcus Meningitis and the Identification of the Meningococcus for the Standard Methods Committee on Diagnostic Procedures and Reagents.

encountered a few strains that grow well at room temperature, and have had 3 strains, typical meningococci in all other respects, that were maintained for nearly a year by transplanting, incubating, and storing entirely at 20° C.

Some strains are inagglutinable when they are first recovered from patients. Practically all of these can be coaxed to agglutinate later, though they do not do so in time to supply a criterion for diagnosis. Many experienced workers do not consider agglutination necessary for identification of the meningococcus.

A more complete definition of the meningococcus would therefore be:

A Gram-negative coccus, usually occurring in pairs with flattened adjacent sides, which ferments dextrose and maltose with the production of acid, forms characteristic colonies, does not produce yellow pigment, usually grows at incubator temperatures, and is, as a rule, at some time agglutinable by polyvalent antimeningococcic serum.

Microörganisms having all of the above characteristics are certainly meningococci, but not all meningococci have each and every one of these characteristics.

The inclusion of agglutinability by polyvalent antimeningococcic serum in the definition of the meningococcus will be opposed by many on the very logical grounds that new serological groups, unrepresented in the serum, may be encountered; and also that strains fulfilling other requirements are considered meningococci whether they are agglutinated or not.

DISTRIBUTION

The normal habitat of the meningococcus is the naso-pharynx. In meningococcus infections it may be found in the cerebrospinal fluid, either intracellularly or extracellularly, in the blood, or in the petechiae of the skin. These are the usual sources from which the meningococcus is obtained.

DIAGNOSTIC PROCEDURES

Cerebrospinal fluid—This is usually obtained by lumbar puncture, the special needle for this purpose being inserted in the 3rd or 4th lumbar space. The size of the needle used depends to a certain extent upon the size of the patient, though sometimes a very thick and viscid fluid will make a large needle necessary in a child. An 18 gauge needle of 3 or 4 inches in length is the size in most common use, though 17 gauge may be necessary if the fluid is very thick, and 19 gauge is preferred by some. In small children, 20 and even 22 gauge of 2 inch length may be indicated. In cases where the spinal canal is blocked, cisternal puncture may be resorted to, and special needles are made for this purpose. This is not often necessary for an early diagnostic puncture.

The spinal fluid should be collected directly into several tubes, preferably at least three. This is especially important when the first fluid is blood tinged, for the presence of blood interferes with some of the examinations to be made. In some laboratories the rule is to use the second tube for cultures, and the third for cell counts, glucose determinations, and other chemical tests. Other individuals prefer the last tube for cultures. It is difficult to get an even suspension for counting if conical centrifuge tubes are used to collect the fluid.

The amount of fluid withdrawn, whether or not it is under increased pressure, and its appearance, *i.e.*, whether blood tinged or yellow, the degree of cloudiness, etc., should be recorded, and the fluid should then be sent immediately to a laboratory for examination. It should be kept warm, if possible, in this interval.

There are certain laboratory procedures which must be done immediately if they are to be of value. Chief among these is the cell count. The sample of

fluid should be free from blood, and the distribution of the cells should be even. Sometimes the fluid may be placed directly, without dilution, in a counting chamber, 9 large squares counted, and the result multiplied by 10/9 to obtain the number of cells found in 1 cu. mm. If the cells are too numerous to count by this method, the fluid may be diluted in a "white counting" pipette, as for a regular leucocyte count.

Special detailed directions for counting cells in cerebrospinal fluid may usually be found accompanying the counting chambers. The pamphlet prepared by the Arthur H. Thomas Company to accompany the Levy Chamber with the improved Neubauer ruling directs that the diluting fluid be drawn up to the mark "1" on the usual Thoma white cell pipette, and that the spinal fluid then be drawn up into the bulb and to the engraved mark above the bulb. After mixing, the first 2 or 3 drops are discarded, a subsequent drop placed in the counting chamber, and *5 minutes* allowed for the cells to settle. All cells in the entire ruling are counted and multiplied by 10/9 to ascertain the number of cells in 1 cu. mm. A special diluting fluid for cerebrospinal fluids is:

Methyl violet	0.2 gm.
Glacial acetic acid	10 c.c.
Distilled water	90 c.c.

This should be filtered to insure absence of artefacts.

Some workers feel that all spinal fluids should be diluted, even though only slightly turbid, to insure the absence of all red cells.

The practical value of a cell count is questioned by Dr. J. B. Neal[4] on the following grounds: it is difficult to obtain a uniform mixture of cells, not only because they settle out rapidly, but because the cell content varies among the several tubes collected; thus comparison of the count from day to day may be of no value or even misleading. Dr. Neal's opinion on this matter is also shared by others.

A differential count of the spinal fluid cells should also be made at this time. With very cloudy fluids smears for this purpose can be made without centrifugation; if the fluid is only slightly cloudy it may be centrifuged first and the sediment used. It must be remembered that leucocytes are fragile and that centrifugation hastens their destruction. Wright's stain, used as for blood smears, or May-Grünwald followed by Giemsa may be employed.

The May-Grünwald stain can be purchased by the pint ready for use. The method, as used by Dr. John Hays Bailey at the Municipal Contagious Disease Hospital in Chicago, is as follows:

1. Flood the slide with the stain, leave it on for 3 minutes, and then pour off. The slide may be washed with distilled water, but this is unnecessary. Do not blot. The preparation is not over-stained if left longer, *provided that it does not become dry.*
2. The diluted Giemsa is then poured on it (for 1–10 Giemsa, 10 minutes is average; for 1–15, 20 minutes is best. The methyl alcohol used for the Giemsa *must* be acetone free).
3. Wash thoroughly with distilled water from a wash bottle until the preparation has a pink color.

The differential count is a special aid in diagnosis with spinal fluids that are only slightly turbid. The predominance of polymorphonuclear leucocytes will aid in ruling out tuberculous meningitis, poliomyelitis, encephalitis, and lymphocytic choriomeningitis (aseptic meningitis, or serous meningitis).

Quantitative determinations of sugar in spinal fluid are done routinely in many laboratories, and are considered to be very important, not only as an aid to diagnosis, but in prognosis and in following the course of the infection.[4] Sugar determinations should be done at once and cannot be made in a blood-

tinged fluid. An adaptation of the method of Folin and Wu[5] to cerebrospinal fluids is found in the laboratory manual of Kolmer and Boerner,[6] and is quoted at the end of this report.

Direct precipitation tests upon the cerebrospinal fluid may often be of great value in arriving at an early diagnosis. For such a test to be successful it is important that the serum used should be rich in precipitins and that the spinal fluid should be obtained before serum therapy is begun.

Rake[7] has described such a test in which he has used monovalent rabbit sera especially high in specific group precipitins, and thus he has obtained information as to the "type" of meningococcus involved within a period of 2 hours instead of having to wait 2 or 3 days to ascertain this. He emphasizes the fact that negative results are apt to be obtained with spinal fluids in which the meningococci are few, thus causing very little specific substance to be present. His technic, which is also suitable for use with polyvalent sera, is essentially as follows:

One-tenth c.c. of serum is placed in a precipitation tube, and 0.1 c.c. of spinal fluid is layered over it. It is examined at once for a "ring" at the point of junction and incubated at 37° C. A reading is again made after 1 hour and then the tube is thoroughly shaken and replaced in the water-bath. Another reading for precipitate is made at 2 hours and the tubes are then placed in the icebox over night, at which time a final reading is made.

A stained smear of the centrifuged spinal fluid sediment is an important factor in early diagnosis. Dr. Scott, of the British Ministry of Health, reports that it is much easier to find meningococci in such smears if they are stained with watery, methylene blue or carbolthionin, and that smears so stained should always be looked at first, and a Gram-stained preparation examined after this. In some laboratories only the Gram-stained preparation is made. The flattened Gram-negative diplococci may be very abundant, both within and without the leucocytes; on the other hand, it may require careful search to detect them, and sometimes they cannot be found. A half hour is none too long to look for them. These stained smears should be made and examined as soon as possible.

Care should be taken not to jump at the conclusion that any Gram-negative bacteria seen are meningococci, for the Pfeiffer bacillus is very pleomorphic in spinal fluid and some Gram-positive cocci may seem Gram-negative in such smears. If Gram-negative diplococci are found they should be reported as such, and not called meningococci without further identification.

Further identification consists in cultivating the organism on a suitable medium, and examining its morphology in pure culture, its cultural characteristics, and its action upon dextrose and maltose, as well as its failure to ferment saccharose and levulose. The identity of the microörganism may be reported at this point. Corroboratory evidence can be obtained by agglutination with polyvalent serum, and this is especially valuable in the case of strains in which fermentative powers are not well developed. It must be remembered that some freshly isolated strains are inagglutinable. It is not absolutely necessary that the strain should agglutinate with polyvalent serum in order to be called a meningococcus.

The culture medium used for isolation of the meningococcus depends much on the laboratory or individual using it. Our own preference at the National Institute of Health is for 5 per cent rabbit's blood agar, made with a meat infusion base, and for a modification of the Hitchens'[8] simple semisolid 0.15 per cent agar medium made

from a beef infusion broth of pH = 7.4.* Some laboratories prefer adding 0.1–0.2 per cent dextrose to these media. Workers at the Rockefeller Institute use the following three media for isolation from spinal fluid, emphasizing that they must be both moist and warmed to 37° C.: (a) 4 per cent rabbit's blood "pneumococcus agar" plates, (b) semi-solid ascitic agar tubes, and (c) serum dextrose agar slants. They also favor planting two sets of these media and incubating one set under slightly increased CO_2 pressure. After the organism is isolated they prefer the rabbit's blood "pneumococcus agar" plate for identification.

For primary cultures the New York City Laboratories inoculate the following: red blood streak plate, glucose semi-solid stab, nutrient broth, coagulated blood agar slant, and a plain agar slant for control. They report that the largest number of positive cultures is obtained in the semi-solid medium.

The laboratories of the Municipal Contagious Disease Hospital in Chicago found a simple semi-solid agar medium so successful that they have discontinued the use of any other, using only it for isolation from spinal fluids.

The New York State Laboratories employ blood agar plates and a dextrose semi-solid medium, the plates being incubated in 5–10 per cent CO_2.

The British Ministry of Health reports inspissated egg as the favorite medium for isolation from spinal fluid, especially if the meningococci are scanty, or if the fluids have been sent from a distance, but prefer 10–20 per cent serum agar or 5 per cent blood agar for identification.

Thus we see that although there may be considerable variation in the details of technic in the isolation of meningococci from spinal fluid, the blood agar plate and the tube of semi-solid agar, with or without enrichment, remain the general favorites in practically all hands. All are agreed that a generous inoculum should be used; many insist that only centrifuged sediment should be used, though others use the uncentrifuged spinal fluid when the meningococci seem to be especially abundant in the stained smear.

The spinal fluid itself as a medium should not be ignored. Incubating it at 37° C. over night often results in a tremendous multiplication of the meningococci so that their detection in smears and their cultivation are made much easier. The New York State Laboratories incubate the sediment remaining after making primary cultures, and plate it daily on 3 successive days. The importance of the spinal fluid itself as a medium is recognized by many laboratories and is of special value in places where proper media are often hard to obtain. Cultures are often obtained from shipped fluids more than 24 hours old if large inocula are used. The British Ministry of Health recommends that specimens of spinal fluid that are to be shipped be mixed with an equal quantity of dextrose broth and incubated for 12 hours before being sent. Most workers try to keep the spinal fluids warm while they await examination, but Dr. Josephine Neal states that she gets her best results by keeping them in an icebox rather than in an incubator.

For fermentation reactions most laboratories seem to prefer a solid medium. A favorite is a 10 per cent ascitic fluid agar containing 1 per cent of the desired carbohydrate and phenol red, litmus, or andrade as indicator (medium 10, New York State and British Ministry of Health). Five per cent serum is added by some instead of the ascitic fluid, and the Rockefeller Institute adds 5 per cent hemolyzed blood to a beef heart agar base.

* Formulae for these media and for others to be described will be found at the end of this report.

Not all laboratories prefer solid media. The Municipal Contagious Disease Hospital laboratory in Chicago uses the ordinary semi-solid agar medium with carbohydrate and indicator added. At the National Institute of Health in Washington, we prefer a simple semi-solid medium made of peptone; 0.15 per cent agar, salts, and carbohydrate, with brom-thymol-blue added—a medium devised by Enlows.[9] This is not a rich medium, and for initial cultures from spinal fluid we have added carbohydrate and indicator to the usual hormone semi-solid media (medium 11). If such cultures are made directly from spinal fluid, it is frequently possible to finish the complete identification of the meningococcus in less than twenty-four hours. Most meningococci grow nicely on the Enlows medium, but especially delicate strains are placed on serum-carbohydrate-agar (medium 10) slants with added indicator (brom-thymol-blue).

For maintenance of cultures of meningococci there are three types of media in favor: (a) semi-solid agar, with or without ascitic fluid and with various modifications, (b) serum dextrose agar slants, and (c) egg slants.

(a) In a simple 0.15 per cent agar medium, with a meat infusion base, cultures of meningococci will usually need to be transplanted about every 2 weeks, though some may live much longer. At the National Institute of Health we have adopted Murray's [10] suggestion that small amounts of KCl and $CaCl_2$ be added. Cultures upon this modified medium are transplanted about once a month (medium 3). With the addition of ascitic fluid (medium 5) this period between transplants may be lengthened to 2 months (New York State Laboratories). There is no doubt in our minds that Murray's EDB [11] medium prolongs the virulence of meningococci, though it does not maintain this quality permanently. The elaborateness of preparation and titration of this medium has prevented its becoming as popular as it deserves to be.

(b) Serum dextrose agar (medium 6) is an excellent medium for meningococci, its drawback being that such cultures are very short lived. Some laboratories transplant them every 48–72 hours, whereas others find once a week sufficiently often. Even so, many laboratories prefer to maintain their most important strains on this medium, feeling that the antigenic and immunizing properties of the strains are preserved best on it. There is very little data on the effect of frequent transplanting required by this medium upon the virulence of the strains.

(c) For longevity of cultures egg slants seem to hold first place. Such cultures, sealed, usually remain viable at 37° C. for over a year. In transplanting such cultures it is important to transfer them first to dextrose serum agar, blood agar, or egg slants, and then 48 hours later put them again on the egg slants on which they are to be stored. There seems to be considerable difference of opinion as to the effect of this medium upon virulence, antigenicity, and serological relationships.

(d) With all of the above media it is understood that incubation and storage are at 35–37° C. Although room temperatures and ordinary icebox temperatures do not permit long viability of meningococci, storage in a frozen state at —15° C. has been found to maintain glycerine covered cultures or glycerine suspensions for more than 2 years.[12] Virulence is also prolonged to some extent by this method of storage.

When agglutination is to be done to confirm the identity of the meningococcus, growth, not more than 24 hours old, from solid media is used. The favorite medium for this purpose is a 0.5 per cent dextrose agar. Growth is

suspended in 0.85 per cent sodium chloride solution of a known pH, and the suspension diluted to a density equivalent to 500 p.p.m. of the silica standards described in *Standard Methods of Water Analysis*.[13] Such a suspension contains, on an average, about 1 billion organisms per c.c., though individual suspensions vary greatly, as do individual strains.

It is important to know the pH of the salt solution used, for a culture that may be inagglutinable at pH = 7.8 may agglutinate nicely at pH = 6.8. Serum dilutions of 1–25 to 1–1,600 or higher should be made, making the final dilutions after the suspension is added 1–50 to 1–3,200. The total amount used in an ordinary sized agglutination tube is 1 c.c., though some prefer smaller tubes and lesser quantities. Normal horse serum in dilutions of 1–25 and 1–50 and a saline control should also be used. This whole test is incubated at 55° C. for 18 hours and then read. Some workers prefer incubation at 37° C. for 2 hours and storage in an icebox over night before reading.[14]

Some laboratories use microscopic slide agglutination. The greatest advantage of this procedure is that individual colonies from a primary culture may be used and a correct diagnosis arrived at quickly. The usual method for performing these is as follows [15, 16]:

Polyvalent antimeningococcic horse serum and normal horse serum are diluted 1–10 with physiological salt solution, and a loopful of each placed on a slide. Some of the suspected colony is emulsified in each, or, some of the colony is emulsified in the normal serum and some of the suspension transferred to the drop of diluted immune serum.

Agglutination may be observed macroscopically and microscopically. Organisms of characteristic morphology and staining, which are agglutinated only by the immune serum, may be tentatively considered meningococci. This method is not used for "typing."

Whether or not it is of value to "type" cultures of meningococci as a routine procedure is still an open question. As an aid in the diagnosis of meningococcus meningitis, and as a help in treatment of the individual patient, its value is uncertain at the present time, since serum used in treatment is entirely polyvalent in this country. Should the technic of preliminary "typing" by a precipitation reaction between spinal fluid and monovalent serum come into general use, it should theoretically be possible to use monovalent serum for treatment. Under these circumstances it would be important to type the meningococcus obtained from the spinal fluid as a confirmation of the precipitin test.

The British have already put these principles into use. Besides the usual polyvalent serum, they use a monovalent group I serum (including "types" I and III) for group I–III infections. For this reason the British Ministry of Health recommends routine "typing" as a guide in serum therapy as well as an index of changes in the serological type prevailing in different areas of the country. They often make use of a precipitin test upon centrifugal spinal fluid to make an early determination of the type, and confirm this later by agglutination of the culture.

Although unnecessary for diagnosis and treatment in the present state of our knowledge and experience, "typing" is of great serological and epidemiological interest, and is well worth doing from these standpoints if the laboratory has time and sera that are sufficiently specific. Information about the "types" or "groups" that are prevalent in a community or in a given epidemic can only be determined in this way.

"If "typing" is to be done, it is essential that the strains of meningococci with which the rabbits are to be immunized are chosen with great care. The serological groups are not clear-cut and almost every degree of "overlapping" can be found. The strains chosen should correspond as nearly as possible to the original type strains described by Gordon and Murray.

A satisfactory method of immunizing rabbits is by 3 courses of intravenous injections of freshly made suspension of young cultures of meningococci on 3 successive days, these series being 1 week apart. A week after the third series a trial bleeding is made, and if the serum is satisfactory the animal is bled from the heart. If the immunization extends over too long a period, the titer of the serum may be increased, but this is apt to be at the expense of specificity and more "cross agglutination" between groups is apt to result.

When strains are being "typed" it is best to include in the test the specific strains with which the sera were made and also a polyvalent horse serum of good agglutinating titer. The British Ministry of Health gets best "typing" results with the I–III group by using absorbed sera.

Blood—It is becoming more and more common to make blood cultures as an aid to diagnosis in meningococcus infections. Especially are these of value in very early cases, and in those without meningeal symptoms. These should be made as soon after the blood is drawn as possible—preferably at the bedside. Small flasks of hormone broth may be used (medium 1), *i.e.*, about 10 c.c. of blood added to 100 c.c. of warmed broth in a 250 c.c. flask. This gives a relatively large surface, which is desirable, as the meningococcus tends to grow at the surface. Semi-solid agar (medium 3) gives good results, as meningococci do not grow easily in liquid media, as a rule. Some people add the blood to hormone agar (medium 2), melted and cooled to 45° C., mix, and pour into Petri dishes. Addition of 0.1–0.2 per cent dextrose to these media may enhance the growth. When initial cultures are obtained, identification of the organism proceeds as usual.

It is with cultures isolated from blood that differentiation from the gonococcus is most often important, though this situation may also arise with cultures from spinal fluid. Definite rules for such differentiation are not easy to set down. The gonococcus is much more exacting in its growth requirements, and shows very small fine colonies on solid media. It ferments only dextrose. It is, as a rule, well agglutinated by polyvalent antimeningococcic serum, and by many of the monovalent sera, especially those of group II, so that agglutination does not make a satisfactory basis for differentiation. Some people who have worked much with gonococci feel that complement-fixation is more reliable.

Petechiae — Although meningococci are present in the petechiae, isolation from them is seldom attempted during life. Occasionally, after death, this procedure allows a diagnosis when other methods are unsuccessful, especially in fulminating cases which have died without showing meningeal symptoms and from which no blood cultures were made. The microörganisms may be seen in properly stained sections (Gram), and they may often be cultivated if the tiny bit of skin is placed in semi-solid media.

Nasopharynx—Very few hospitals and laboratories make nasopharyngeal cultures from cases of meningitis routinely. So it is difficult to know how constantly and for how long the meningococcus is found there. It can be said, however, that those who have looked for it there have frequently found it. Most often nasopharyngeal cultures are made for the purpose of

detecting carriers. In any case, the technic is the same, and is described in great detail in many manuals.

Many people like to use a West tube in making these cultures, as the swab is protected from contamination with the throat flora. Personally I much prefer a simple bent wire swab and an ordinary wooden tongue depressor. These wire swabs have been used extensively by the Army, Navy, and the U. S. Public Health Service, and are described in the pamphlet, *Standard Technique of Meningococcus Carrier Detection*, compiled jointly by them some years ago.[17] The swab is a naked flexible wire about 25 cm. long, with one end well covered by an absorbent cotton pledget, and the other end bent into a loop for a handle. The last 1–2 cm. of the cotton covered end is bent to an angle of about 30–40°.

A straight wooden swab stick is used by some, but it is less easy to obtain satisfactory material with.

In any case the swab should be passed behind the uvula and should be moved gently to and fro over the posterior and upper pharyngeal wall. It should not touch any part of the mouth or throat. A good light is important. In a search for carriers, the subject should sit facing the light. In the case of patients who are ill, a flash or head light may be used.

The blood agar plate is the medium of choice for the isolation of the meningococcus from the nasopharynx. A hormone agar with 5 per cent defibrinated rabbit's blood (medium 2) is our own choice. Dr. Rake, whose recent work with carriers has been intensive, prefers adding 4 per cent rabbits' blood to "pneumococcus agar" (medium 4). For a time laked blood agar plates were used extensively, and some people still prefer them. It has the advantage of making the meningococcus colony appear more translucent, but the disadvantage of not showing the zones of hemolysis or methemoglobin produced by many of the bacteria from which the meningococcus is to be differentiated.

In the usual blood agar plate the translucent meningococcus colonies are easily distinguished from those of the commoner inhabitants of the nasopharynx, except for the other members of the genus *Neisseria*, which are often confused with those of the meningococcus. It must not be forgotten that occasionally meningococcus colonies may be very large.

Differentiation of the meningococcus from other *Neisseria* often requires careful cultural, biochemical, and serological studies for its sure identification. This makes carrier detection a laborious procedure.

Sometimes the proportion of meningococci to other bacteria in the nasopharynx will be very small; at other times it may be found in practically pure culture.

The suspected colonies are ringed and a Gram-stained smear made from a part of each. If this smear shows Gram-negative cocci of typical morphology, the colony is picked to a blood agar or serum dextrose agar slant and incubated at 37° C. The next day cultures are made to test its fermentation reactions, it is transferred to semisolid agar to keep alive for future use, and the remainder of the 18–24 hour growth emulsified in salt solution to use for agglutination with both polyvalent and type sera. If slide agglutination is used at this stage, it should be confirmed later by the test tube method.

It is not necessary to "type" each culture for mere carrier detection, and when such a survey is being made on a large scale it is sometimes advisable, as well as necessary, to omit the "typing." But from an epidemiological point of view, "typing" is very important in carrier surveys, since it indicates the nature of the strains preva-

lent, and often also the trend of an epidemic. For this reason, it is often desirable to "type" the recovered meningococci later if there is no opportunity at the actual time of isolation. "Typing" a strain immediately after its isolation frequently gives a much better idea of its antigenic pattern, since some strains have a tendency to "spread" serologically on prolonged laboratory maintenance, so that it is more difficult later to determine its grouping accurately or its relation to the other strains in a given epidemic.

Inagglutinable strains may be encountered. If these are not true meningococci they will be apt to be agglutinated to a slight extent by normal horse serum, or they may ultimately form a yellow pigment or have peculiar fermentation reactions. If a strain is not agglutinated by normal horse serum, does not form pigment, and ferments dextrose and maltose only, it is fairly safe to consider it a meningococcus. If, however, it fails to ferment one or both of these sugars, as some strains do immediately after isolation, it is important to get serological confirmation of its identity. Sometimes a slight lowering of the pH of the salt solution used in the suspension and serum dilutions will turn the trick (in such a case controls without serum should show that it is not merely an acid agglutination). Sometimes, if a strain is plated out and several colonies picked and studied, one colony will be found to agglutinate. And sometimes an indirect method must be resorted to—a rabbit is immunized with the strain in question and the resulting serum used to agglutinate known meningococci. This last step is seldom necessary in order to get agglutination with a good polyvalent serum, but is not infrequently resorted to in "typing." Usually strains of meningococci that are peculiar in these ways become quite typical in agglutination and fermentation after a more or less long period of laboratory maintenance.

FORMULAE FOR CULTURE MEDIA

1. Beef Infusion Bouillon (National Institute of Health)

(Used as a base in making semi-solid media for stock culture maintenance, and for other media)

Constituents—

1. Beef steak (freed of fat and bone)	500 gm.
2. Peptone (1.0%)	10 gm.
3. Sodium chloride, C.P. (0.5%)	5 gm.
4. Distilled water	1,000 c.c.

Preparation—

1. Remove all fat, bone, and tendons from beef steak and chop into small pieces.
2. Add distilled water, mix well, and allow to infuse in ice chest for not less than 18 and not more than 24 hours.
3. Remove from ice chest, heat in streaming steam (100° C.) for 1 hour, then under pressure of 15 lb. for 30 minutes.
4. Squeeze through cheese cloth until 1,000 c.c. is obtained. If unable to obtain this amount, restore volume with distilled water.
5. to this broth add:

Peptone	10 gm.
Sodium chloride, C.P.	5 gm.

Mix well, stir until ingredients are dissolved.

6. Adjust reaction, using NaOH solution, to pH 7.6 or desired reaction.
7. Heat in streaming steam (100° C.) for 30 minutes.
8. Determine reaction and, if necessary, adjust to 0.2 points above desired final pH to compensate for the acid drift encountered in sterilization.
9. Filter through moist filter paper.
10. Distribute into chemically clean containers.
11. Sterilize—Steam autoclave, 15 minutes 15 lb. pressure.
12. Incubate for not less than 12 hours at a temperature of 37° C. for a check as to the efficiency of the sterlization procedure.

NOTE: Heavy precipitates of phosphates are occasionally thrown down at time of sterilization, thereby making it necessary to repeat the process of filtration and sterilization; that is, if a clear broth is desired immediately. However, if not needed for immediate use and the medium is allowed to stand for a number of weeks, the phos-

phate precipitates will dissolve, eliminating the process of filtration which extracts valuable nutritive materials.

The prolonged heating period (1 hour at 100° C. and 30 minutes at 15 lb. pressure, Step No. 3) applied to the cooking of the beef infusion, tends to stabilize the corrected reaction of the finished medium.

The color of the finished broth will vary due to the amount of blood pigment in the beef steak used. Prolonged heating and sterilization periods will also affect the color of the finished product.

Various infusion bouillons may be prepared by substituting veal, heart, liver, brain, etc., in place of the beef steak in the above formula and following precisely the same preparation procedure given for the Beef Infusion Bouillon.

2. *Nutrient Agar Agar (National Institute of Health, Washington)*

(Meat Infusion Agar)

(Used as base in making blood agar plates, semi-solid agar medium for serum-carbohydrate slants for fermentation, and for dextrose agar for shipping cultures)

Round steak, free from fat, chopped fine	500 gm.
Tap water	1,000 c.c.

Mix and let stand in icebox for not less than 18 hours and not more than 24 hours.

Heat in streaming steam (100° C.) for 1 hour and under pressure of 15 lb. for 30 minutes.

Squeeze through cheese cloth until 1,000 c.c. is obtained. If unable to obtain this amount make up loss with water.

To this broth add:

Peptone	10 gm.
Sodium chloride C.P.	5 gm.

Adjust reaction, using NaOH solution, to pH 8.0.

Heat in streaming steam for 30 minutes. To this broth add:

Shredded * agar-agar	20 gm.

* Powdered agar-agar may be used in place of the shredded agar-agar, but the following steps are required: sprinkle the powdered agar-agar on the surface of the bouillon; let stand until the agar-agar has dropped to the bottom of the container; stir briskly; then heat.

Stir thoroughly.

Heat in streaming steam for 1 hour and under pressure of 15 lb. for 30 minutes.

At this point turn out flame under autoclave. Do not open pet cocks. This will allow pressure to drop slowly. Do not open sterilizer for at least 18 hours. This will allow agar to solidify and all precipitates which have dropped to bottom of container may be cut off when the agar is slipped from the container.

The clear portion is melted and, after adjusting to pH 7.6, is filled into the desired containers and sterilized.

Sterilization: Autoclave 15 minutes 15 lb.

For blood agar plates, melt the above nutrient agar. Cool to between 42 and 45° C., add 5 per cent defibrinated rabbit's blood, mix and pour. Horse or sheep blood may be used instead of rabbit.

For semi-solid agar, see formula 3.

For serum carbohydrate slants see formula 10.

For dextrose agar slants, 1 per cent or 0.5 per cent dextrose is added to this medium. With this medium the carbohydrate may be added directly, or, even better, a 20–50 per cent solution, sterilized by heat, may be kept on hand, and enough added before dispensing to make the desired concentration.

3. *Semi-solid Agar Medium for Meningococci (National Institute of Health)*

(A modification of Hitchens's Medium)

Constituents—

1. Beef infusion bouillon (pH 7.4)	2,700 c.c.
2. Nutrient agar-agar	300 c.c.
3. Potassium chloride, KCl C.P.	0.6 gm.
4. Calcium chloride, $CaCl_2$ C.P.	0.3 gm.

Preparation—

1. Melt agar and heat bouillon to 100° C.
2. Mix agar and broth well.
3. Add potassium chloride and calcium chloride.
4. Stir until thoroughly dissolved.
5. Determine reaction and, if necessary, correct to pH 7.3.
6. Dispense into tubes.
7. Sterilize—15 minutes, 15 lb. pressure.
8. Incubate for not less than 12 hours at a temperature of 37° C. for a check as to the efficiency of the sterilization procedure.

4. *Pneumococcus Agar (Rockefeller Institute)*

Fresh beef heart (free from fat and gristle)	500 gm.
Witte peptone	10.0 gm.
Sodium chloride	5.0 gm.
Agar	20.0 gm.
Dextrose	0.3 gm.
Tap water	1,000.0 c.c.

For meningococci, 100 c.c. of citrated rabbits' blood are added to each 250 c.c. of medium, and plates poured.

5. *Semi-solid Ascitic Agar (Rockefeller Institute)*

Heart muscle (free from gristle)	1 lb.
Distilled water	1,000 c.c.
Peptone (Witte's)	10 gm.
NaCl	5 gm.
1 per cent agar	0.25 gm.

Chop meat and infuse in water over night in refrigerator. Heat infusion to 85° C. for 30 minutes. Filter through Prat-Dumas filter paper No. 50 and make up to original amount with distilled water. Add peptone and NaCl and bring to the boil. At boiling point adjust pH to 7.8 and add agar. Heat in Arnold for 1 to 1½ hours. Filter through absorbent cotton into flasks and sterilize at 116° to 118° C. for 20 minutes in the autoclave. The final pH should be 7.6 to 7.4.

To this agar, when melted and cooling, add an equal amount of sterile ascitic fluid.

6. *Glucose Semi-solid Medium (New York City Department of Health)*

Nutrient veal infusion broth	1,000 c.c.
Dextrose	1%
Agar	0.25%

Adjust reaction to pH 7.2–7.4. Tube and sterilize in Arnold apparatus for 1 hour on 2 successive days. This medium should be firm enough to hold its shape when gently inverted, should offer no resistance to the needle, and should be semi-fluid when at incubator temperature.

7. *Serum Dextrose Agar Slants (Rockefeller Institute)*

To 400 c.c. of stock 2 per cent agar add 80 c.c. of sheep serum water; sterilize in Arnold for ½ hour. Cool slightly and add 1 per cent dextrose.

Sheep serum water—1 part serum to 3 parts water which is sterilized in the Arnold for 3 consecutive days for 30 minutes. It is resterilized just before adding.

Dextrose solution—A 50 per cent solution sterilized in the Arnold for 2 consecutive days for 30 minutes.

8. *Solidified Egg Medium*

(Modified Dorsett's Egg Medium) (National Institute of Health)

Constituents—

1. Fresh eggs	4 eggs
2. NaCl solution (0.85% solution)	25 c.c.

Preparation—

1. Scrub eggs with brush in soap and water. Allow eggs to dry.
2. Place eggs in wire basket and dip into 95 per cent alcohol. Allow to remain a few seconds, after which time it is withdrawn and the small amount of alcohol which still remains on the basket and eggs is ignited in order to remove the alcohol and help sterilize the shells.
3. The shells are then broken using aseptic technic and the whites and yolks placed in a sterile container.
4. Add 25 c.c. of sterile 0.85 per cent NaCl solution.
5. Mix well with sterile beater.
6. Filter through sterile cheese cloth.
7. Dispense into sterile tubes.
8. Slant in an inspissator, heat very slowly until solidified. Do not allow heat to rise above 76° C.
9. Cool and incubate.

9. *"Chocolate" Coagulated Blood Agar (National Institute of Health)*

Constituents—

1. Sterilize veal Infusion agar (see note below)	100 c.c.
2. Fresh, sterile, defibrinated, sheep blood	10 c.c.

Preparation—

1. Melt agar (keep sterile).
2. Cool agar to 45° C.
3. Add sterile sheep blood and mix well.
4. Heat slowly in Arnold sterilizer or in a water-bath. Allow temperature to rise very slowly until medium has a very definite chocolate color. Excessive heating will cause blood to coagulate and the finished medium will show clumps of cooked blood instead of the uniform, smooth, chocolate color desired.

5. Dispense into sterile containers and allow to cool.

6. Incubate for not less than 12 hours at a temperature 37° C. for a check as to the efficiency of the sterilization procedure.

NOTE. Veal infusion agar is prepared according to the directions given for beef infusion agar substituting the same amount of veal in place of the round steak. All other ingredients remain the same and the preparation steps are to be followed exactly as listed.

10. Solid Medium for Fermentation Tests (New York State Laboratories and National Institute of Health)

Sugar-free beef-infusion agar, 2% with indicator		200 c.c.
Carbohydrate 10.0% solution	1% or	20 c.c.
Ascitic fluid	10% or	20 c.c.

Procedure—

Melt the agar and cool to 50° C.

Add carbohydrate and ascitic fluid (both previously warmed to 50° C.) .

Mix well and dispense.

Slant tubes immediately to solidify.

Incubate for 48 hours at 37° followed by 48 hours at room temperature.

Examine for contaminants.

The carbohydrate solution has been sterilized by filtrations through a sterile Berkefeld candle.

In some laboratories the serum or ascitic fluid is omitted.

11. Semi-solid Media for Fermentation Tests (National Institute of Health)

(This is usually medium 3 with indicator and 5 per cent of a filtered 20 per cent solution of the desired carbohydrate added.)

12. Enlows's Sugar Free Medium (Semi-solid) for Fermentation Tests

Peptone	5.0 gm.
Na_2HPO_4 (sodium phosphate)	7.2 gm.
KH_2PO_4 (potassium phosphate)	0.7 gm.
Agar-agar	2.0 gm.
Tap water	900.0 c.c.

The above substances are mixed well and heated for 30 minutes at 100° C. (streaming steam) and then given 15 lb. pressure for 15 minutes in the autoclave.

Filter through moist filter paper while hot. Keep solution as hot as possible during filtration process.

Three drops of concentrated brom-thymol-blue solution is added to every 500 c.c. of the clear filtered solution. The color corresponds to pH = 7.6 in the brom-thymol-blue color range.

Pour into suitable containers and sterilize 15 minutes at 15 lb. This is the basic medium.

Carbohydrate solutions are prepared as follows:

Distilled water	100 c.c.
Carbohydrate	4.5 gm.

Mix thoroughly and sterilize by filtering through a sterile Berkefeld filter.

The above solution (100 c.c.) is added to 900 c.c. of the sterile basic medium and mixed.

Dispense into sterile tubes.

Incubate 48 hours to check sterility.

13. Preparation of Concentrated Brom-Thymol-Blue Indicator (National Institute of Health)

Brom-thymol-blue (dibromo-thymol sulphonphthalein) finely pulverized	1.0 gm.
N/20 NaOH	32.0 c.c.

Grind together in a mortar until in solution.

QUANTITATIVE ESTIMATION OF SUGAR IN CEREBROSPINAL FLUID

(Kolmer and Boerner. *Approved Laboratory Technique,* 1931, p. 242)

Principle—

Proteins present are precipitated by tungstic acid and determination is carried out by the Folin-Wu method, using 1–5 dilution of filtrate.

PROCEDURE

1. With a 1 c.c. pipette transfer 1 c.c. of spinal fluid to a *clean, dry* test tube.
2. Add with a pipette 3 c.c. distilled water.
3. Using a graduated 1 c.c. pipette, add 0.5 c.c. of 10 per cent sodium tungstate.
4. Add 0.5 c.c. of ⅔ normal H_2SO_4.
5. Mix well and let stand 5 to 10 minutes.
6. Filter.
7. Pipette 2 c.c. of the clear filtrate into a Folin-Wu sugar tube and proceed as with blood. See "*Blood*" below.
8. Calculation, using standard 1:

$$\frac{20}{R} \times 50 = \text{mg. dextrose per 100 c.c. fluid.}$$

R = reading.

9. Pipette and test tubes should be abso-

lutely clean and dry or the error will be large.

10. If the cerebrospinal fluid contains a little blood, centrifuge and use the clear supernatant fluid.

For Blood—

1. Pipette 2 c.c. of tungstic acid blood filtrate into a special Folin sugar tube.
2. To a similar tube, add 2 c.c. of standard sugar solution B, and to a third add 2 c.c. of standard sugar solution C, containing 20 mg. dextrose per 100 c.c.
3. To each tube add 2 c.c. of the molybdate phosphate solution.
4. Transfer the tubes to a boiling water-bath and heat for 6 minutes.
5. Cool for 2 to 3 minutes in a cold water-bath without shaking.
6. Add to each tube 2 c.c. of the molybdate phosphate solution.
7. Let stand for 3 minutes; dilute the resulting solution to the 25 c.c. mark.
8. Insert a rubber stopper and mix.
9. Compare in a colorimeter with the nearest matching standard set at 20.

The two standards are adequate for practically all cases as they cover a range from about 70 to nearly 400 mg. of dextrose per 100 c.c. of fluid tested.

REAGENTS FOR BLOOD SUGAR DETERMINATIONS

Alkaline copper tartrate solution:

Dissolve 40 gm. of pure anhydrous sodium carbonate in about 400 c.c. of distilled water in a liter flask. Add 7.5 gm. of tartaric acid, and when this is dissolved add 4.5 gm. of crystallized copper sulphate. Mix and make up to a volume of 1 liter.

Test for the absence of cuprous copper by transferring 2 c.c. to a test tube and adding 2 c.c. of the molybdate phosphate solution; the deep blue of the copper should almost completely vanish.

If the chemicals used are not pure, a sediment of cuprous oxide may form in the course of 1 or 2 weeks. If this happens, remove the clear supernatant reagent, or filter through a good quality filter paper. Test for copper. This reagent keeps indefinitely.

Molybdate-phosphate solution:

Transfer 70 gm. of molybdic acid (C. P. Bakers analyzed "special") to a liter beaker. Add 10 gm. of sodium tungstate, 400 c.c. of 10 per cent sodium hydroxide, and 400 c.c. of distilled water. Boil vigorously for 20 to 40 minutes (to remove ammonia present in molybdic acid). Cool, and dilute to about 700 c.c. Add 250 c.c. of concentrated (85 per cent) phosphoric acid. Dilute to 1,000 c.c.

The solution should be water clear. If it has a yellow tinge the chemicals used are not pure enough and there will be an error in the determination.

Benzoic acid:

Dissolve 2.5 gm. benzoic acid in 1 liter of hot water and cool. Transfer to a bottle; the solution will keep indefinitely. Filter as necessary.

Standard sugar solutions:

A. Stock—Weigh 1 gm. of pure dextrose (glucose) on an analytical balance and dissolve in about 50 c.c. of the benzoic acid solution. This 1 per cent standard stock solution keeps indefinitely.

B. Standard containing 10 mg. dextrose per 100 c.c.—Pipette 5 c.c. of stock solution into a 500 c.c. volumetric flask and dilute to the mark with benzoic acid solution.

C. Standard C containing 20 mg. dextrose per 100 c.c.—Pipette 10 c.c. of stock solution into a 500 c.c. volumetric flask and dilute to the mark with benzoic acid solution.

Diluted standards B and C should be made fresh every month.

Serological Tests for the Diagnosis of Syphilis*

THE trends indicated by the volume of specimens received for examination suggest that each year greater reliance is placed by physicians and health officials on the results of serological tests as an aid in the diagnosis and as a guide for the treatment of syphilis. The value of the procedures at present in general use in North America is thus emphasized. This situation, however, should not inhibit efforts toward further improvement. A still greater sensitivity is probably desirable; also simplification of procedures would, without doubt, result in a much wider application of such tests.

The data obtained in the study of serological tests for syphilis conducted under the auspices of the U. S. Public Health Service [1] are in general accord with the results of the investigation of the problem undertaken for the Committee on Standard Methods of the Laboratory Section of the American Public Health Association.[2] In both instances, the findings suggest that the complement-fixation test can, with safety, be made somewhat more sensitive than precipitation tests; also that these two types of procedures as developed in the United States and Canada differ in relative efficiency from those represented at the conferences at Copenhagen [3] and Montevideo,[4] sponsored by the League of Nations, where the results indicated that the complement-fixation tests were less satisfactory than some of the precipitation tests with which they were compared. The reactions reported by Dr. Kahn, who participated in all of the studies, furnish an excellent basis for comparative analysis.

The findings with specimens from lepers secured in the recently completed investigation were of special interest. A thorough study of the behavior of sera from patients with this disease is indicated. The high incidence of yaws or syphilis in some of the countries where leprosy is prevalent complicates the problem.

The desirability of employing a presumptive technic for the selection of specimens which would require further study was suggested to your committee last year. A similar recommendation was included in the report of the committee acting for the U. S. Public Health Service.[1] Such a procedure would not only facilitate the work, but also encourage a more careful study of the specimens selected for evaluation. A presumptive complement-fixation procedure with a sensitive cholesterolized antigen, less than two units of complement, and fixation over a prolonged period at from 3 to 6° C., followed by incubation at 37° C., should provide an adequate means for detecting specimens which would fail to react in completely controlled tests with such antigens. The use of a relatively small amount of complement should result in reactions being indicated even with specimens which give more marked fixation with small rather

* Report of the Referee on Methods for the Serological Diagnosis of Syphilis for the Standard Methods Committee on Diagnostic Procedures and Reagents.

than large amounts of serum. With the majority of specimens from patients with syphilis, more sensitive reactions have been obtained with cholesterolized antigens than with non-cholesterolized. Specimens which react with the non-cholesterolized antigen only are encountered so rarely that the adoption of a procedure for their detection would seem unnecessary. In a presumptive procedure, controls for anticomplementary properties would not be required since any specimen with which evidence of a significant degree of fixation occurred would be carefully tested.

The use of an oversensitive precipitation test should, in a similar manner, permit the selection of sera that would fail to react in more delicately adjusted tests of this type.

In many laboratories, entirely negative findings are obtained with at least 75 per cent of the specimens received, and 25 per cent of them, or less, either give reactions of varying degrees or are anticomplementary, or for some other reason are not satisfactory for the test. A presumptive procedure should, of course, be oversensitive, but should be so adjusted that under the conditions just mentioned approximately 70 per cent could be promptly excluded as failing to react. The remaining 30 per cent could then be studied fully. The saving of time and materials that would result might be illustrated by a concrete example. With 400 specimens per day, preliminary complement-fixation and precipitation procedures which would employ one tube each (without controls) would require 800 tubes. If negative findings were obtained with 70 per cent of the specimens, reports could be sent promptly on 280 of them. Assuming 8 tubes would be used for fully controlled complement-fixation and precipitation tests on the remaining 120 specimens, 960 additional tubes would be needed or a total of 1,760 tubes, while if a complete test with 8 tubes had been employed on the original 400 specimens, 3,200 tubes would have been required. As an increasingly large proportion of specimens is collected from persons undergoing physical examinations, those admitted to hospitals, and similar groups where the percentage of reacting sera is found to be small, the greater will be the saving in time and materials if a presumptive method is used.

Having the preliminary procedures as well as the final tests handled independently by two groups of workers would furnish protection against technical inaccuracies.

The use of presumptive tests may be inhibited through a fear of obtaining oversensitive results. Preliminary procedures without controls would not have this disadvantage, since diagnostic significance would be attached only to negative findings secured by this means.

By reducing the work with specimens which fail to react, quantitative procedures might be employed with some of the other sera, especially those which give partial or atypical reactions; for example, those which have been found to give reactions with one antigen only or at one temperature only. Careful studies of such specimens might be helpful, particularly in instances where the patients are not found to have a definite history or definite clinical manifestations of syphilis. A means for the evaluation of the relative specificity of the fixation obtained would be especially desirable in such cases. The procedure described by Wadsworth, Maltaner, and Maltaner,[5, 6] provided the technic could be made applicable for complement-fixation tests for syphilis in which small amounts of serum are used, may furnish a method for determining the significance of reactions of the type mentioned, as well as those secured with specimens from lepers and the ones occasionally ob-

tained with blood from patients having malaria, tuberculosis, and other febrile diseases.

Preliminary findings indicate that presumptive procedures of the type outlined would markedly facilitate the work of a routine nature without jeopardizing accuracy. Also, the comparatively small percentage of specimens with which partial reactions are obtained should permit them to be studied fully, thus facilitating the wider use of the test, in view of the greater economy, and also providing additional information in regard to reactions of the type which, under present conditions, sometimes offer particular difficulties of interpretation.

Tentative Methods for the Cultivation and Isolation of Tubercle Bacilli and the Production of Tuberculin*

I. General statement
II. Preparation of specimen for examination
III. Preparation of reagents
IV. Preparation of culture media
V. Production of tuberculin (Koch's A.T.)

Cultural Method for the Primary Isolation of M. Tuberculosis

The cultural method for the isolation of *M. tuberculosis* has now gained wide recognition. It has been found to be quite as reliable in most instances as the method of guinea pig inoculation and has the advantage of being more economical and time saving. Guinea pig inoculation should be carried out on specimens of urine.

Method of Procedure—One of the most important steps in the preparation of routine specimens for the culture of tubercle bacilli is the method of treating the specimen in order to eliminate the contaminating organisms, which would hinder or obscure the growth of the tubercle bacillus. It is also essential that whatever form of treatment is instituted, it should not kill any tubercle bacilli present in the specimen.

1. The specimen as received is placed in a sterile 6" test tube, care being taken to deliver it to the bottom of the tube. This is done to prevent, as far as possible, contaminating the side of the tube. The tube is well flamed and a sterile cotton plug is inserted.

2. Equal parts of 3 per cent hydrochloric acid containing bromcresol purple is added to the specimen. Should there only be a sedimented specimen, 5 c.c. of this reagent is added. This acid solution is 3 per cent of the concentrated hydrochloric acid, and is not 3 per cent hydrogen chloride.

3. After the addition of the 3 per cent hydrochloric acid solution to the specimen, the tube is shaken by a side to side motion and the upper portion of the tube is well flamed to within an inch of the upper level of the liquid. A fresh sterile cotton plug is inserted in the tube.

4. The partially treated specimen is left at room temperature for 2 hours, after which time it is neutralized by the addition of 3 per cent sodium hydroxide to pH 7.0. This reagent is added aseptically to the tube.

5. A rubber cap is placed over the tube, in order that the overlapping cotton plug will be held in place. The neutralized specimens are then centrifuged at high speed for ½ hour.

6. After centrifugalization, the supernatant fluid, to within ½" from the top of the sediment, is withdrawn by means of a suction apparatus, which is attached to a rubber tubing to a flask containing phenol.

7. By means of a platinum loop, a beef infusion broth culture is planted with a loopful of material from each specimen. These broth cultures are incubated at 37° C. for 24 hours, and then examined for turbidity in the liquid.

8. These broth cultures indicate whether or not all extraneous organisms have been destroyed in the treatment process.

9. All the specimens showing no growth on the broth are then planted by a sterile capillary pipette on various types of media suitable for growing the tubercle bacillus.

10. After planting, the upper portion of the culture tube is flamed, the cotton plug is ignited, and inserted in the tube. A rubber cap (previously boiled for 15 minutes) is placed over the end of the tube.

---

* Report of the Referee and Associate for Tuberculosis and the Tubercle Bacillus for the Standard Methods Committee on Diagnostic Procedures and Reagents.

11. The specimen is incubated for 8 weeks at 37° C. The cultures are examined at the end of 4 weeks for visible growth. Cultures showing visible growth at this time are examined and reported. Cultures showing no growth after 4 weeks' incubation are reincubated for a further 4 weeks.

12. Many types of culture media have been used and the following have been found satisfactory: Lowenstein's, Petragnani's, Woolley's medium with and without glycerine, and modified Petroff's medium. Lowenstein's medium has been found to support growth the best.

Preparation Reagents—The reagents used for the treatment of these specimens, 3 per cent hydrochloric acid solution and the 3 per cent sodium hydroxide solution are sterilized by autoclaving 20 minutes at 15 lb. pressure; 0.08 gm. of the indicator bromcresol purple is added to the hydrochloric acid solution before sterilization. These reagents are then placed in a glass cabinet to exclude air-borne contaminants. A siphon apparatus with a bottle attached is placed in each flask. When not in use the glass case is kept closed.

MEDIA

Lowenstein's Culture Medium

Ann. de l'Inst. Pasteur, 50:161–166 (Feb. 13), 1933. See also *Tubercle,* IV:502–504 (Aug.), 1933.

1. 20 eggs carefully cleansed by immersion for ½ hour in tepid soapy water to which is added 5 per cent sodium carbonate
2. Asparagin solution: Asparagin (Merck) grammes 3; K_2HPO_4 (potassium phosphate, Merck) 1 gm.; Pure crystalline magnesium sulphate (Kahlbaum) 1 gm.; Pure glycerin 30 B. (Kahlbaum) 60 c.c.; Distilled water 1,000 c.c. This solution is sterilized for 2 hours in flowing steam. It is very stable.
3. Potato starch
4. Congo red (Grubler) 2 per cent aqueous solution sterilized in autoclave for 15 minutes
5. Malachite green (Grubler) 2 per cent aqueous solution sterilized in flowing steam for 2 hours

To 600 c.c. of the asparagin solution one adds 10 c.c. of a 50 per cent solution of potato starch and 60 c.c. of juice pressed from sterile tomatoes. This mixture is boiled for 2 hours in a water-bath. After cooling to 50° C., 16 eggs are added and then the yolk of 4 eggs. Then this mixture is actively stirred and 20 c.c. of Congo red solution is added.

After stirring, it is filtered through 4 layers of gauze. Then it is put in sterile tubes. Coagulation is produced by heating to 75–80° C. in flowing vapor. The tubes are carried to the oven and the next day it is again heated for 2 hours at 75–80° C. To cap the tubes use cellulose.

The culture media should be prepared oftener than every 2 weeks and kept in the dark.

Lowenstein's Media as Used in Studies Carried Out in the Ontario Department of Health:

Asparagin solution	1,000 c.c.
Potato flour	8.3 gm.
Tomato juice	100 c.c.

Boil in double boiler for 2 hours, cool to 45° C., and add:

Whole eggs	26
Egg yolks	8
2 per cent malachite green	34 c.c.

Strain through gauze, tube and sterilize.

Lowenstein's Medium with two dyes and sodium silicate is made as above, but with the addition of 34 c.c. 2 per cent Congo red solution and 0.5 c.c. of 1.9 per cent sodium meta silicate 9 H_2O per 100 c.c. of medium. This gives approximately 2 mg. SiO_2 per 100 c.c.

In making the asparagin solution, chemicals of any standard C.P. brand are used.

Tuberculosis Culture Media

Coagulated egg is the basis of many tuberculosis culture media. The coagulation and sterilization of these media cause considerable trouble. The following procedure is recommended:

The tubes of media in slant racks are placed in a cold autoclave. The racks are covered with newspapers to prevent too sudden contact with the steam. The autoclave is closed and the air outlet valve also closed. Pressure is raised to 15 lb. without letting the air escape. This condition is maintained for 10 minutes. The air outlet valve is then slightly opened (the pressure should not be allowed to vary more than ½ lb.), and the condensed water and some air are allowed to escape. All the air should not be allowed to escape. The valve is then closed and sterilization continued for 15 minutes.

Petroff's Medium

J. Exper. Med., 21:38–42 (Jan.), 1915.

Two parts of egg (white and yolk)
One part of meat juice
Gentian violet sufficient to the proportion of 1 to 10,000

Meat juice: 500 gm. of beef or veal are infused in 500 c.c. of a 15 per cent solution of glycerin in water. Twenty-four hours later the meat is squeezed in a sterile meat press and collected in a sterile beaker.

Eggs: Sterilize the shells of the eggs by immersion for 10 minutes in 70 per cent alcohol or by pouring hot water upon them. Break the eggs into a sterile beaker and, after mixing the eggs well, filter through sterile gauze. Add 1 part by volume of meat juice.

Gentian violet: Add sufficient 1 per cent alcoholic gentian violet to make a dilution of 1 to 10,000.

Tube about 3 c.c. in each sterile test tube and inspissate for 3 successive days: on the first day at 85° C., until all the medium is solidified, changing the places of the tubes if necessary; on the second and third days for not more than 1 hour at 75° C. For the bovine type omit the glycerin and infuse the meat for 24 hours in water. Bovine tubercle bacilli grow in this medium even if it contains glycerin, but on account of the popular belief and the lack of data we used a medium without the glycerin.

The following modification is used in the Laboratories of the Ontario Department of Health:

Milk	200 c.c.
Nutrient broth (not adjusted)	200 c.c.
Eggs	800 c.c.
Glycerin	60 c.c.
Malachite green 2 per cent (aqueous)	60 c.c.

NOTE: Nutrient broth—0.3 per cent beef extract, 0.5 per cent P.D. Peptone, 0.5 per cent sod. chloride

Mix well, stain through gauze, tube, slant and sterilize.

Herrold's Media as Modified by Feldman

J. Infect. Dis., 48:236, 1931.

Beef Extract Agar

Liebig's beef extract	3 gm.
Peptone	10 gm.
Sodium chloride	5 gm.
Agar	15 gm.
Distilled water	1,000 c.c.

Adjust media to pH 7.5.

Autoclave 15 minutes at 15 lb. pressure.

To each 150 c.c. of melted agar add the yolk of one egg, when temperature of agar is 60° C.

Allow agar egg yolk mixture to cool to 40° C., then dispense in tubes.

NOTE: Sterilize egg shell by immersion in phenol, or flame one end of the shell. By means of a pair of flamed forceps, make an opening. Allow the egg white to escape, then by means of a sterile pin or needle, puncture the yolk, allowing the yolk to mix with beef extract agar.

Potato Egg Medium for the Isolation of Tubercle Bacilli

J. S. Woolley and F. G. Petrik, *Am. Rev. Tuberc.*, Nov., 1931, pp. 596–603.

Autoclave medium sized unpeeled potatoes for 30 minutes at 15 lb. pressure. Peel and, after thorough mashing, suspend in 15 per cent glycerol-water, in the proportion of 500 gm. of original potato to 500 c.c. of 15 per cent glycerin. Heat in a boiling water-bath for 30 minutes, stirring occasionally. Strain through two layers of surgical gauze by compression into a flask and then boil filtrate for about 5 minutes. Cool and add 1 part of filtrate to 2 parts of well beaten whole fresh egg. Add sufficient 1 per cent crystal violet to make a concentration of 1 to 30,000. Stir thoroughly, to distribute the dye evenly throughout the mixture. Pour the mixture through one layer of sterile gauze into a tubing funnel and add approximately 7–8 c.c. of medium to each tube. Sterilize in the inspissator at the proper slant for ½ hr. at 85° C. on the first day, and at 75° C. on the second day.

Bring inspissator up to required temperature before introducing tubes. By omitting the crystal-violet an excellent medium is obtained for growing stock cultures of tubercle bacilli. Incubate the tubes to test for sterility. Tubes must be stored, seeded, and incubated in an upright position to keep the surface of the medium dry.

Modification used in the Laboratories of the Ontario Health Department:

Potato	1,000 c.c.
Water (no glycerin is used)	1,000 c.c.
Monobasic potass. phosphate	14 gm.

Filtrate from above..........	900 c.c.
Malachite green 2 per cent sol.	34 c.c.
Crystal violet 1 per cent sol.	6.5 c.c.

Petragnani's Medium

C. F. Cerruti, *Brit. J. Trop. Med. & Hyg.*, May, 1932, pp. 157–158.

Preparation of Medium

Milk	160 c.c.
Granular Potato starch (Fecula)	6 gm.
Peptone	1 gm.

Place these ingredients in a liter flask with pieces of a peeled potato the size of a hen's egg. Take the flask by the neck and put it in boiling water, shaking vigorously. When it has formed a colloid dough, stop shaking and leave in the boiling water-bath for 1 hour. Take it out and leave until the temperature is down to 60° C. Add 4 whole eggs and 1 yolk.

It is not necessary to sterilize the flask or milk, or to treat the eggshells. Now add:

Glycerin	12 c.c.
Malachite green 2 per cent aqueous solution	10 c.c.

Stir until it becomes a homogeneous mass and filter the mass through sterile gauze into a sterile flask; fill into sterile tubes (20 cm. by 22 mm.), or plates, using 12 c.c. to 15 c.c. of medium for each. Solidify in an inspissator in the following manner: Place the tubes or plates in the inspissator when it is still cold, bring it slowly to a temperature of 85° C., keep it at this temperature for 25 to 30 minutes, and leave to cool. This treatment is usually sufficient to solidify and to sterilize the medium, but its nutritive properties are not damaged by a tyndallization of 15 minutes at 80° C. the first day, and 10 minutes at 75° C. for two successive days.

The bovine strain will not grow well in the presence of glycerin, and when the material is suspected of containing a bovine strain two sets of cultures should be made, one with Petragnani's usual medium and one without glycerin, using bovine bile instead.

Modification used in the Laboratories of the Ontario Department of Health:

900 c.c. milk
36 gm. potato flour
6 gm. Peptone
6 pieces of potato (size of an egg)
24 eggs
6 egg yolks
72 c.c. glycerine
60 c.c. 2 per cent aqueous malachite green

Cut the potatoes into thin slices. Add milk, potato flour, and peptone. Cook in a double boiler for 2 hours, stirring until the mixture becomes sticky, then stir occasionally. Break the eggs and egg yolks into a 2 liter flask; shake well. Add the glycerine and malachite green and shake. Cool the potato milk mixture to 45°–50° C. Add egg glycerin mixture to the cooled potato mixture and mix well. Filter through gauze, tube and sterilize.

Egg Yolk for Growth of Tubercle Bacilli

Herrold. *J. Infect. Dis.*, 48:236. *Medium* is as follows:

Beef extract agar prepared as follows:

Liebig's beef extract............	3 gm.
Peptone	10 gm.
NaCl (mixture adjusted to pH 7.5)	5 gm.
Agar	10 gm.
Distilled water	1,000 c.c.

The yolk of 1 egg is added to 150 c.c. of melted agar at a temperature of 60° C. This is approximately 15 per cent of egg yolk. The agar is allowed to cool to about 40° C. and dispensed in tubes. A simple method of adding egg yolk is to flame one end of the egg and crack it with sterile forceps, so that a small opening is made in the shell for discarding the white, after which the yolk is broken with a sterile platinum loop to permit its flow into the container of melted agar. The egg may be immersed in phenol and then alcohol before flaming, or it may be placed in boiling water for 1 minute after preliminary flaming. The incubator should be kept moist to prevent drying of the plates, although it has been noticed that the yolk agar plates do not dry so quickly as blood agar plates. Closed containers may be used when the incubator is not sufficiently moist, or the plates may be wrapped with tin foil.

PREPARATION OF TUBERCULIN (KOCH'S A.T.)

Medium—

Asparagin (Pfanstiehl)	5.0 gm.
Ferric amm. citrate (Bakers)..	0.05 gm.
Mag. sulphate (Bakers)........	1.0 gm.
Pot. acid phosphate (Bakers)..	3.0 gm.
Amm. citrate (Bakers)........	5.0 gm.
Sodium chloride (Merck)......	2.0 gm.
Sodium carbonate (Merck)....	1.0 gm.
Glycerol (Bakers)	50.0 c.c.
Distilled water	1,000.0 c.c.

Dispensed in 150 c.c. amounts in 1 liter flasks. Sterilized in the autoclave at 120° C. for 1 hour.

Strain—Human strain of tubercle bacillus known as "Johnston." It is of moderate virulence such that 0.5 mg. of the moist culture will cause the death of the guinea pig in 6 to 8 weeks.

Time of Incubation—A small amount of the surface growth from a previous batch is transferred to each flask and allowed to remain at 37° C. for 4 months. At the end of this time the flasks are removed from the incubator, placed in an Arnold sterilizer and kept in free-flowing steam for 1 hour. The contents of the flasks are filtered through hardened filter paper (Whatman's No. 50). The filtrate is concentrated in a water-bath at 85° to 90° C. to one-tenth of the original volume of the medium. The concentrate is centrifuged at high speed, the supernatant removed and 0.3 per cent phenol is added and stored at 5° C.

TESTS FOR NONSPECIFIC TOXICITY, STERILITY AND STANDARDIZATION

Nonspecific Toxicity Test — Five c.c. are injected subcutaneously into a normal guinea pig and observed for 3 months, at the end of which time a complete autopsy is performed.

Sterility Test—Samples are taken from each container and tests made in fluid media according to the standards for sterility testing.

Standardization—A sample of the International Standard Old Tuberculin is received every 6 months from the Permanent Commission on Biological Standardization of the League of Nations, as distributed from Hampstead, London, and is used as the standard.

TEST FOR POTENCY

The Intradermal Test in guinea pigs is the method used for standardization. Six white guinea pigs of approximately 300 gm. are sensitized with human tubercle bacilli receiving 0.5 mg. of moist culture. Four weeks after the injection of the tubercle bacilli the hair is removed from the backs of the guinea pigs by using a fine electric clipper. The backs are then marked off into areas by means of an indelible pencil.

The following dilutions are made of (a) the Test Tuberculin and (b) the Standard Tuberculin: 1 in 500; 1 in 1,000; 1 in 2,000; 1 in 4,000. Each guinea pig is inoculated intradermally with 0.1 c.c. of each dilution of the two tuberculins; the dilutions of the Test Tuberculin along one flank and those of the Standard Tuberculin in corresponding sites of the opposite flanks. The reactions are read in approximately 24 hours after the injections and comparison made of the two tuberculins.

INTRADERMAL TESTS IN THE HUMAN OR THE MANTOUX TEST

The initial dose should be 0.01 mg. contained in 0.1 c.c. If negative the test should be repeated using 1.0 mg. in 0.1 c.c.

A. L. MACNABB, *Referee*
M. H. BROWN, *Associate Referee*

Tentative Methods for the Recognition of the Brucella Group of Organisms and Other Biological Procedures as They Relate to the Diagnosis of Undulant Fever*

Isolation Procedures

BLOOD CULTURE

Citrated Blood[1]—Receive blood in sterile rubber stoppered culture tube containing sufficient dry sterile sodium citrate to give a final concentration of 1 per cent per 10 c.c. A 10 c.c. sample is sufficient for culture. A 1 per cent concentration of sodium citrate will prevent phagocytosis of any organisms present in the blood.

Incubate the citrated blood sample in 10 per cent carbon dioxide at 37° C. Draw off a 0.3 c.c. sample every 3 days and run over the surface of a liver infusion agar slant. Reincubate the blood sample and examine all slants carefully for growth at the 3 day intervals. If the slants show the presence of contaminants, add all further samples of blood to liver infusion slants containing gentian violet in a 1:200,000 concentration. Make smears from suspicious slants and examine for Gram-negative cocco-bacilli. Continue this procedure until the specimen is used up or until a suspicious organism has been isolated. Isolate suspicious Gram-negative cocco-bacilli in pure culture on liver agar plates plus gentian violet and identify by agglutination, hydrogen sulphide production, and dye tests.

Maintain pure cultures of *B. melitensis* and *B. suis* on liver infusion slants in air and pure cultures of *B. abortus* on the same medium in 10 per cent carbon dioxide until they will grow in air.

Inactivated Blood[2]—The blood sample should be inactivated for 30 minutes at 55° C. immediately after it has been removed from the patient. Place the

* Report of the Referee on Serological, Bacteriological, and Other Biological Procedures in the Diagnosis of Undulant Fever, for the Standard Methods Committee on Diagnostic Procedures and Reagents.

sample in a flask containing 50 c.c. of liver infusion broth and incubate in 10 per cent carbon dioxide at 37° C. Observe at 3 day intervals, and run 0.3 c.c. sample over the surface of a liver infusion slant when the first sign of turbidity appears. Then follow the procedure as outlined under Citrated Blood. Incubate the blood sample at least 1 month.

URINE [1]

Centrifuge a 50 c.c. sample of urine at 3,000 r.p.m. for 1 hour. Spread the sediment over the surface of two liver infusion agar plates containing gentian violet in a 1:200,000 dilution. Incubate the plates in 10 per cent carbon dioxide at 37° C. for 72 hours and examine. Brucella colonies appear light blue violet in color on gentian violet plates. Transfer suspicious colonies to a second gentian violet plate if contaminants are present or to plain liver infusion agar if they are not. Identify the organism by agglutination, by hydrogen sulphide production, and by dye tests. Aerobic types of Brucella will not be inhibited in 10 per cent carbon dioxide.

FECES [3]

Mix 1 gm. of feces in 50 c.c. of sterile physiological salt solution and shake to obtain a thorough suspension. Filter the suspension through four layers of hospital gauze to remove gross particles. Centrifuge at 500 r.p.m. for 3 minutes to throw down other particles and other bacteria. Remove the supernatant suspension to another tube, and add sufficient agglutinating serum to make a dilution of 1:100. Shake and place the tube in a 37° C. water-bath for 2 hours. Centrifuge at 500 r.p.m. for 5 minutes and discard the supernatant. Resuspend the precipitate in physiological salt solution, shake and recentrifuge. Discard supernatant fluid. Repeat this procedure twice. Spread the precipitate over the surface of two eosin methylene-blue agar plates containing a 1:200,000 concentration of gentian violet. Incubate in 10 per cent carbon dioxide at 37° C. for 72 hours. Transfer suspicious colonies to a second gential violet plate if contaminants are present or to liver infusion agar plates if they are not. Identify the organism by agglutination, by hydrogen sulphide production and by dye tests. Aerobic types of Brucella will not be inhibited in 10 per cent carbon dioxide.

MILK

See *Standard Methods of Milk Analysis* for this procedure.

GUINEA PIG INOCULATION [1]

Guinea pigs are inoculated with, (1) blood, (2) urine sediment, and (3) milk.

Blood—Inoculate one guinea pig subcutaneously with 2 c.c. of blood from specimen received for culture. At the end of 8 weeks, anesthetize the animal and withdraw sufficient blood for an agglutination test. Kill the animal and culture the spleen pulp, heart's blood, urine, and bile on liver infusion agar. Make duplicate plates for each specimen. Incubate one set in 10 per cent carbon dioxide and the other in air at 37° C. Observe the plates at 3 day intervals for suspicious colonies. Make smears and examine for Gram-negative cocco-bacilli. Identify as indicated under Identification Procedure.

Urine — Centrifuge uncatheterized specimens of urine and follow the procedure for Blood. Inject animals with 2 c.c. specimens of catheterized urine.

Milk—See *Standard Methods of Milk Analysis* for this procedure.

BLOOD SERUM AGGLUTINATION TEST
With Unknown Serum
TEST TUBE METHOD [1]

Preparation of Antigen—Prepare a monovalent antigen with a type strain of *B. abortus*. Inoculate liver infusion agar Blake bottles with saline suspensions of 72 hour liver infusion agar cul-

tures of the organism. Incubate the Blake bottles in air at 37° C. for 72 hours. Remove the growth from the agar surface with a solution of 0.5 per cent phenol in 0.85 per cent salt solution. Make smears to determine purity of suspensions. Filter suspensions through several layers of hospital gauze to remove particles of agar. Unheated antigens are satisfactory and are recommended. Store the concentrated antigen until ready for use. For routine tests, dilute the antigen concentrate with phenolized salt solution to a turbidity 7 cm. Gates. Diluted antigen will remain satisfactory at room or coldroom temperature for 1 year. Check the antigen with known antisera of high, medium and negative titer.

The test—Bring samples and antigen to room temperature. Prepare serum dilutions on the multiple or decimal system. Add antigen and shake tubes to mix serum and antigen. Incubate in a water-bath at 55° C. for 4 hours and hold at room temperature or in the coldroom over night before reading. Record complete agglutination by a plus sign (+), incomplete agglutination with a plus-minus sign (±) and negative agglutination with a negative sign (—).

RAPID METHOD [1]

Antigen dropper pipette—Prepare capillary pipettes by drawing out glass tubing ⅛" inside diameter. Cut the capillary end at a diameter 0.07". Do not flame delivery end of pipette. This pipette should deliver 0.03 c.c. antigen in each drop.

Glass plate and darkfield illumination box—Rule of a 6½" x 14" piece of double thickness window glass in 1" squares with a diamond point pencil. Set the glass on the top of a box 12" long x 10" wide x 6" deep with one side of the top covered to a width of 3½". Place a light bulb under the covered portion of the top to provide direct illumination. Paint the inside of the box directly behind and above the light white and the remainder black.

Serum amounts—Use 0.08, 0.04, 0.02, 0.01 and 0.004 c.c. of serum in the test. These volumes, when added to 2 c.c. of antigen in the tube test give final dilutions of 1–25, 1–50, 1–100, 1–200 and 1–500.

Preparation of Antigen—See "Brucella Infections in Animals and Man," by I. Forest Huddleson, for detailed procedures for the preparation and standardization of rapid antigen.

The test—Bring samples of serum and antigen to room temperature. Shake antigen thoroughly and at 2 hour intervals during sample testing. Test 6 sera at one time; 0.08, 0.04, 0.02, 0.01 and 0.004 c.c. amounts of each serum to be tested in each row marking from the bottom to the top of the row. Place a drop of antigen on each drop of serum. Hold the pipette vertical so that the volume of the drop delivered will be correct. Mix the serum and antigen for each serum with a fresh toothpick working from the bottom to the top of each row. Lift the plate and tilt back and forth for 2–3 minutes. Place plate back on box, turn on light, and read results. Results may be read in serum amounts or serum dilutions. Turn off light as soon as results are read. Scrub the plate with washing powder, rinse in tap and distilled water and wipe dry with a clean chamois skin.

With Unknown Organism

TEST TUBE METHOD

Use the same procedure for agglutination as outlined under Agglutination Test, with unknown serum. Use an abortus antiserum [4] prepared as follows: Prepare antisera in rabbits. Dilute a suspension of an avirulent strain of *B. abortus* to a turbidity of 7 cm. with the Gates apparatus. Kill the suspension by heating for 1 hour at 56° C. Inject 1 c.c. of suspension subcutaneously on 2 consecutive days. On the third date in-

ject 0.5 c.c. intravenously. One week from the first injection inject 1 c.c. of heated suspension intravenously. Repeat this dose for the next 2 days. One week from the fourth injection inject 1 c.c. of heated suspension intravenously. Inject the live saline suspension from one-half of a liver infusion agar slant intravenously daily for the next 2 days. Rest the animal 1 week, and inject the live saline suspension from one-half of a liver infusion agar slant intravenously. Inject the live suspension from one whole slant intravenously daily for the next 2 days. Rest the animal for one week. Inject the live suspension from one whole slant intravenously daily for 3 days. Make test bleedings to determine the titer and bleed the animal to death from the heart if the titer is satisfactory. If not, repeat the schedule of the last week until test bleedings indicate a satisfactory titer. The schedule produces an antiserum with a titer of 1 to 2,560.

MILK SERUM AGGLUTINATION TEST [5]

Let the samples of milk stand for 6 to 8 hours to allow cream to separate. Pipette off as much cream as possible and place samples in tubes. Add 2 drops of rennet to each 5 c.c. portion of milk and mix thoroughly. Incubate tubes at 37° C. in a slanting position so that the curd and serum will separate. The serum will form in about 2 hours. The samples should be placed in a cold-room for 6 to 8 hours to obtain sera free from particles of casein. Test the clear serum in the same manner as blood serum. Do not test sour milk, colostrum, or milk in which the curd has become partially digested. Samples of milk should be iced if they are to be in transit more than 10 hours.

DYE BACTERIOSTASIS [1]

Liver Infusion Agar—See preparation of medium under Determination of Hydrogen Sulphide production.

One per cent stock thionin solution, aqueous—

Use the following formula to prepare a 1.0 per cent stock solution:

a. Formula

Certified thionin $1 \times \dfrac{1}{\text{total dye content}}$

Distilled water up to 10.0 c.c.

b. Procedure

Weigh dye and add to distilled water in a culture tube. Boil for 15 minutes in a water-bath.

One per cent basic fuchsin solution—

Use the following formula to prepare a 1.0 per cent stock solution:

a. Formula

Certified basic fuchsin $1 \times \dfrac{1}{\text{total dye content}}$

Distilled water up to 10.0 c.c.

b. Procedure

Weigh dye and add to distilled water in a culture tube. Boil for 15 minutes in a water-bath.

Thionin liver infusion agar plates—Melt French squares of liver infusion agar in flowing steam or water-bath. Heat stock solution of thionin for 20 minutes in flowing steam or water-bath. Add sufficient 1.0 per cent thionin solution, *while still hot,* to each bottle of liver infusion agar to make a dye concentration of 1 to 50,000. Whirl bottles to mix thoroughly and pour into sterile Petri dishes.

Fuchsin liver infusion agar plates—Melt French squares of liver infusion agar in flowing steam or water-bath. Heat stock solution of basic fuchsin for 20 minutes in flowing steam or water-bath. Add sufficient 1.0 per cent basic fuchsin solution, *while still hot,* to each bottle of liver infusion agar to make a dye concentration of 1 to 25,000. Whirl bottles to mix thoroughly and pour into sterile Petri dishes.

The test—Divide each thionin plate into equal segments. Divide each fuchsin plate into equal segments. Spread a heavy loopful of each culture over one

segment of one thionin and one fuchsin plate. Incubate plates for 72 hours at 37° C. and record presence or absence of growth as indicated below under Recording. Care should be taken not to confuse a heavy inoculum for growth.

Recording—Indicate results according to the following key:

Growth	*Symbol*
Present	+
Absent	—

Classification—Classify the strain according to the following key:

Growth		
Thionin	*Basic Fuchsin*	*Classification*
+	+	*B. melitensis*
—	+	*B. abortus*
+	—	*B. suis*

HYDROGEN SULPHIDE PRODUCTION [1]

Lead acetate paper—Prepare strips of lead acetate paper as follows: Dissolve 10 gm. of lead acetate normal, C.P. grade, in 50 c.c. of boiling distilled water. Immerse sheets of filter paper in the acetate solution until saturated. Dry paper in incubator at 37° C. Cut paper in strips measuring 2½" x ¼". Store in stoppered bottles.

Liver infusion agar—Prepare liver infusion agar slants according to the following formula:

a. Formula

Agar, Bacto	20 gm.
Tap water	500 c.c.
Liver infusion	500 c.c.
Peptone, Bacto	10 gm.
Sodium chloride, C.P......	5 gm.

b. Procedure

Grind fresh, fat-free beef liver to a plastic mass. Mix 1 lb. of ground liver with 500 c.c. of tap water. Cover the container and place in flowing steam for 20 minutes. Remove cover and stir to mix thoroughly. Continue heating for 1½ hours. Filter through 30 mesh wire screen. Add ingredients in above formula to 500 c.c. of liver infusion. Steam for 1 hour. Cool to 60° C. and adjust to pH 7.0. Steam for ½ hour. Decant and tube in 5 x ¾" tubes. Autoclave tubes for 25 minutes at 121° C. The pH should drop to 6.6 during sterilization.

c. Checks

Incubate for 48 hours at 37° C. to check sterility.

The test—Inoculate a liver infusion agar slant with a large loopful of each culture to be tested. Insert a strip of lead acetate paper between the cotton plug and tube wall so that the strip projects 1" below the bottom of the cotton plug. Incubate at 37° C. for 24 hours. Record the absence or presence of blackening on the lead acetate paper as indicated below under Recording. Remove the strip of lead acetate paper and insert a fresh strip. Save each lead acetate paper so that final interpretation may be made from the four papers for each strain. Incubate at 37° C. for 24 hours and record results. Repeat this procedure until the production of hydrogen sulphide has been observed for 4 successive days.

Recording — Record results under "H_2S Production" of report form. Record the H_2S production for the first 24 hours under 1, for the second 24 hours under 2, and so on. Record results according to the following key:

H_2S Production	*Symbol*
None	—
Trace	Tr.
Moderate to marked.....	+

Classification—

Classify each strain according to the following key:

H_2S Production	*Classification*
None or trace for 4 days..	*B. melitensis*
Moderate to marked for the first 2 days........	*B. abortus*
Moderate to marked for 4 days	*B. suis*

BRUCELLA NUCLEOPROTEIN INTRADERMAL TEST—HUDDLESON [1]

Preparation—Grow a smooth strain of *Br. abortus* separately for 72 hours at

37° C. on liver infusion agar in monel metal trays 6" wide, 10" long and ½" deep. The tops of the trays are fitted with a cover of the same metal, but slightly larger in size. At the end of the incubation period lift the growth from the surface of the medium with a celluloid spatula and suspend in a large volume of distilled water. Recover the cells immediately in a Sharples laboratory centrifuge and dry in vacuum over H_2SO_4 at 37° C. The procedure used in obtaining the nucleoprotein fraction from the dried cells was chosen for the purpose of preventing as far as possible chemical alteration of the protein. Carry the separation out rapidly at 5° C. and with suitable precautions to prevent enzymatic decomposition.

Grind a 100 gm. portion of the dried cells in a ball mill to a fine white powder and extract at room temperature for two 5 day periods each with 500 c.c. of anhydrous ether. Decant the solvent and collect the residue on a Buchner funnel and wash with ether. Transfer the air-dried residue from the ether extraction to a small porcelain ball mill together with 200 gm. of cracked ice made from distilled water, and rotate the mill for 2 hours. During the period of rotation add another 100 gm. of ice to maintain a low temperature. At the end of the rotation period add 300 gm. of cold water and allow the mill to stand for 5 hours in the icebox. Shake occasionally by hand. Decant the contents of the mill, the stiff foam being cut with ether. Grind the remaining residue in the mill for another hour with 200 gm. of cracked ice and water and wash from the mill with cold water.

Make the total combined volume of the extracts from the mill to 2 liters. Pass the combined extracts through a Sharples centrifuge several times to separate the cellular material. The final liquid should be clear and slightly yellow. Precipitate the clear extract at a pH of 3 by the addition of 1:1 acetic acid. Allow precipitation to continue for 24 hours in the cold. Separate the precipitate from the supernatant liquid by decantation and centrifuging. Suspend in cold water by drawing it through a fine cloth by suction. Stir the suspended material mechanically and cool with ice while N1 NaOH is added from a burette to alkalinize and effect solution. Keep the pH below 11. Precipitate the solution with 1:1 acetic acid and redissolve in slightly alkaline water three times. Reprecipitate the alkaline solution with 1:1 acetic acid; wash the precipitate twice with distilled water and then dehydrate first with alcohol, then with acetone and ether. Dry the grayish white residue in vacuum over sulphuric acid. Solution of the dried residue is effected in physiological salt solution brought to a pH of 7.4 with N1 NaOH. Sterilize the solution by passing through a sterile Berkefeld W candle. The recovered filtrate is clear and colorless. It is now ready for standardization based on total nitrogen content. The sterile recovered liquid should be diluted with sterile physiological salt solution so that 0.1 c.c. (one skin test dose) contains approximately 0.000015 gm. of nitrogen. It may be placed in sterile vials and sealed until ready for use. The diluted nucleoprotein fraction appears to retain its potency for an indefinite period.

Technic and Interpretation—Make the test by injecting 0.1 c.c. of the fluid intracutaneously in the lateral surface of the forearm, using a 26 gauge needle. The size of the local reaction, which is characterized by a circumscribed erythema and slight edema, may vary from 1 to 3" in diameter. Read the reaction 24 hours after injection. It may persist for 48 to 96 hours. There is rarely, if ever, any necrosis or sloughing of the tissue at the point of the local reaction. In the infected, the local reaction may be accompanied by a more marked manifestation of the present

symptoms. Those that are hypersensitive will show a severe systemic reaction along with the local reaction. Those that have not been sensitized to Brucella and who are probably susceptible to infection show no local or systemic reaction. Often one sees in certain normal individuals an erythema about ½" to 2" in diameter with no edema around the point of the injection. It has the appearance of a nonspecific reaction.

OPSONO-CYTOPHAGIC TEST [1]

Blood Specimen—Collect a 5 c.c. sample of blood in a sterile vial containing sufficient sodium citrate to make a concentration of 0.8 per cent. Keep the specimen in the coldroom until the test is made. Blood samples must be examined within 6 hours to prevent the disintegration of the polymorphonuclear leucocytes.

Bacterial Suspension—Prepare a fresh suspension daily from a 48 hour liver infusion agar culture. Suspend several loopfuls in saline at pH 7.0 to a turbidity of 2 mm. Gates. Suspensions of any of the three species of Brucella are satisfactory so long as they do not become fast to ingestion. Test cultures to "fastness" against immune citrated blood.

The test—Place 0.1 c.c. of whole blood and 0.1 c.c. of bacterial suspension in a clean culture tube. Mix the contents thoroughly and incubate at 37° C. for 30 minutes. Do not resuspend the cells after incubation. Place a small drop of cells on the end of a clean glass slide with a fine capillary pipette. Spread the drop with a second slide as in the preparation of a blood smear. Dry the slide rapidly before an electric fan. Cover the slide with Hastings solution for 15 seconds, then add 1 c.c. of distilled water. At the end of 10 minutes wash the slide free from stain with distilled water. Dry the slide before the electric fan.

Degree of Opsono-cytophagic activity—Count 25 polymorphonuclear leucocytes and record the degree of phagocytosis as follows:

Negative	no phagocytosis
Slight.......	1 to 20 bacteria per cell
Moderate..	21 to 40 bacteria per cell
Marked..	40 or more bacteria per cell

Compare the degree of phagocytosis with the results of the intradermal test and the agglutination test in order to arrive at a diagnosis.

The following system of diagnosis has been proposed by Huddleson:

A PROPOSED SYSTEM FOR THE DIAGNOSIS OF UNDULANT FEVER ACCORDING TO THE RESULTS OF THE AGGLUTINATION, ALLERGIC, AND OPSONO-CYTOPHAGIC TEST

Agglutination Test	*Allergic Skin Test*	*Opsono-Cytophagic Power of Blood*	*Status Toward Brucella*
—	—	Zero to 20 per cent of cells, slight	Susceptible
—	+	Zero to 40 per cent of cells, marked	Infected
+	+	Zero to 40 per cent of cells, marked	Infected
—	+	60 to 100 per cent of cells, marked	Immune
+	+	60 to 100 per cent of cells, marked	Immune

Tentative Methods for the Bacteriological Diagnosis and Control of Whooping Cough*

The Cough Plate Technic for Isolating B. Pertussis

COUGH PLATE MEDIUM

The cough plate [1] used for the isolation of *B. pertussis* is prepared with a modification of Bordet and Gengou's potato blood agar.[2]

Base:

Peeled sliced potatoes....	500 mg.
Glycerine, U.S.P.	40 c.c.
Distilled water	1,000 c.c.

Boil the potatoes in glycerine and water until soft. Make up to volume, strain through gauze and allow to stand for sedimentation. Siphon off the supernatant liquid.

To 500 c.c. clear potato extract add:

Sodium chloride solution, 0.75%	1,500 c.c.
Agar, Bacto	60 gm.

Let stand for 15 minutes to saturate the agar. Heat until the agar is dissolved and dispense in amounts convenient for storage. Autoclave for 25 minutes at 15 lb. pressure (120° C.). This base may be stored indefinitely.

Finished medium—To the melted base, at 45° C., add blood to make a final concentration of at least 15 per cent. The blood should be used when fresh, never more than 72 hours after it has been obtained. It may be from sheep, horse, or human source, but avoidance of horse blood for the vaccine medium is recommended. Mix the blood with the base by whirling, and pour into plates—about 15 c.c. per Petri plate. Either glass plates or metal boxes may be used.

Checks — Incubate several plates from each lot made for 24 hours at 37° C. to check sterility. Inoculate one plate with *B. pertussis* to check the growth promoting ability, colony appearance, and characteristic hemolytic zone.

Satisfactory plates should be bright cherry red in color, and free from bubbles and lumps of agar. They may

* Report of the Referee on Methods and Reagents for the Diagnosis and Control of Whooping Cough for the Standard Methods Committee on Diagnostic Procedures and Reagents.

be used as long as they remain moist and red, usually 2 to 3 weeks if kept in the cold room.

EXPOSURE OF COUGH PLATES

Hold the uncovered plate 4 or 5 inches from the patient's mouth during several expulsive coughs. If necessary, induce a cough by tickling the throat with a swab, pressing on the larynx, giving a drink of ice water, or some other device. Cover the plate as soon as possible after obtaining cough in order to avoid contaminants from the air.

INCUBATION AND EXAMINATION OF PLATES

As soon as possible after the plates have been inoculated, place them in the incubator at 37° C. Examine them several times during the first 48 hours for molds or other spreading colonies which might overgrow the plate, and cut these out with a sterile needle or scalpel. After about 48 hours, search for colonies of *B. pertussis* using a hand lens. Examine the glass plates by transmitted light, placing them uncovered over an ordinary substage lamp. Examine the aluminum plates by reflected light, placing the lamp on end and tilting the uncovered plate in front of the light which will come from the side. If such plates are questionable, transfer the medium to a glass Petri plate and examine by transmitted light. Examine all plates twice daily until *B. pertussis* is found or the negative ones until they have been discarded—6 days after they were received.

CRITERIA FOR IDENTIFICATION OF B. PERTUSSIS COLONIES

Colony appearance—*B. pertussis* colonies appear smooth, raised, glistening, pearly and almost transparent, while the colonies of Gram-positive cocci in general appear duller, darkly colored, and opaque. They are surrounded by the characteristic zone of hemolysis—a zone which is not sharply delimited but merges somewhat diffusely into the surrounding medium.

Consistency of the growth—The consistency of the growth and the manner of its diffusion into water are typical of *B. pertussis*. As a loop of growth touches a drop of water or salt solution, it spreads and shows at first a momentary clumping effect but with very slight agitation it quickly smooths into a homogeneous suspension.

Morphology and staining reaction—Stained by Gram's method, *B. pertussis* decolorizes readily—much more readily, in fact, than does *H. influenzae*. Viewed microscopically, the small, faintly-stained coccoid bacilli are scattered evenly throughout the film, occurring singly for the most part, seldom in chains of even 2, and not found as pleomorphic threads. Frequently they show bipolar staining.

Agglutination tests — Questionable colonies may be tested by a *slide agglutination* technic. Suspend the colonies to be tested in a drop of saline on a slide and mix a loopful of this suspension with a loopful of *B. pertussis* antiserum diluted 1:10. Observe for immediate agglutination, in comparison with the remaining suspension to which serum was not added. For larger amounts of culture and for quantitative results use the *rapid agglutination technic*, described later.

Identification by sub-culture—If a questionable colony cannot be identified with certainty, make a sub-culture to a cough plate, spreading the colony over a small area. There will usually be sufficient growth after 24 hours' incubation for a slide agglutination test and stained preparation.

REPORTING THE FINDINGS

Positive plates may be reported as soon as found. Plates showing no colonies of *B. pertussis* on the 4th day

may be reported as negative to date. The plates should be examined for 2 more days, and additional reports made if any plates are found positive.

BIOLOGICAL CHARACTERISTICS AND REACTIONS IN ANIMALS

To encourage antigenic stability of the cultures (see references 3, 4, and 5), they should be kept on Bordet-Gengou medium containing at least 15 per cent blood. When adapted to other media such as the ordinary blood or coagulated blood agar, brain-veal, or plain infusion agar, the cultures are likely to change antigenically and also they are more difficult to maintain. In this outline we are concerned more particularly with Phase I cultures—the term used by Leslie and Gardner to describe the antigenic state characteristic of cultures just isolated from patients with whooping cough.

The *colony appearance* on Bordet-Gengou medium and the *staining characteristics* of *B. pertussis* have been described above under criteria for identification of *B. pertussis* colonies. It may be added that capsules can be demonstrated by proper technic. For this, Lawson[4] developed a method in which Wright's stain is used. The method of Churchman and Emelianoff[9] also gives good results.

Cultivation and biochemical reactions[4, 5, 6, 8, 14]—*B. pertussis* is a strict aerobe and grows best at a temperature of 37° C. Some formula based upon Bordet-Gengou potato-glycerine blood agar seems best suited of all known media to meet the growth requirements.

When adapted to certain other media, the growth is characteristic. On *coagulated blood agar,* after several preliminary transfers with heavy inoculum the growth is fairly profuse but after a few days tends to adhere to the medium and to die out in a relatively short time. In shallow layers of *broth medium,* a viscid, ropy sediment with floating strands, is produced. On *potato slants,* the growth becomes tan colored after several days' incubation, in this respect resembling *B. bronchisepticus* although the color change is less marked. *Litmus milk* is made alkaline after a week or more. On *carbohydrate media* there is no reaction. *Indol* is not formed. *Nitrates* are not reduced.

Serological reactions—Phase I cultures form a homogeneous group with respect to agglutination and complement fixation reaction.[2, 6]

The *rapid agglutination technic*[10] is particularly adapted to the study of *B. pertussis* and is given here:

Antigen preparation—With a stiff bent needle, remove the 48 hour growth of *B. pertussis* on Bordet-Gengou medium and suspend in saline. Filter the suspension through a thin layer of cotton to assure a smooth, satisfactory antigen. Adjust the turbidity to approximately 20 billion organisms per c.c., after comparing a diluted sample with a series of known suspensions—a convenient series includes 1, 2.5, 5, and 10 billion organisms per c.c., respectively.

Note: Have ready a supply of test tube cotton filters, prepared as follows: Shape a thin layer of moistened absorbent cotton around the finger, place on the bent end of a strip of copper wire netting as a support, and insert in a test tube of convenient size—with the free end of the wire strip hooked over the lip of the tube. Shape the cotton against the walls of the tube with a wooden applicator, plug the tube and sterilize. After use for filtration, remove and discard the filter—re-inserting the sterile plug.

For larger filters for use in flasks, wrap the cotton around the outside of a square of wire netting cut from a bias strip and shaped to fit inside the neck of the flask. Cover this with a single thickness of gauze. Suspend the filter by two wires which cross under it, pass through the netting, and hook over the lip of the flask.

Preparation of antiserum—Immunize a rabbit against a Phase I culture of *B. pertussis,* using a 10 billion suspension of a 48 to 72 hour culture on Bordet-Gengou medium, killed by contact with merthiolate 1:10,000, 48 hours or more in the cold room. Inject 3 doses intravenously—0.4, 0.8, and 1.0 c.c., respectively, per kg. weight, at 3 or 4 day

intervals. Make a trial bleeding about 1 week after the third injection. If the agglutination titer ("equivalent" as described below) is approximately 1:20,000 with the homologous culture and with several other recently isolated strains, bleed the rabbit from the heart or carotid. Inactivate at 56° C. for 30 minutes.

Dilution of the antiserum—A scheme for diluting the serum such as follows is convenient for a series of tests in which no more than 2 c.c. of each serum dilution will be required.

Dilutions lower or higher, or in a closer range, and smaller or larger quantities may be prepared as indicated.

The agglutination test—Mix 0.1 c.c. of each serum dilution with 0.1 c.c. of antigen, the measurements being made with 1 c.c. pipettes graduated in 10ths. For an antigen control, mix 0.1 c.c. of saline with 0.1 c.c. of antigen.

Shake the mixture by hand for 3 minutes, rocking the racks at the rate of approximately 60 back-and-forth motions per minute, and in such a way that the contents flow about three-quarters of the length up the tube.

After the period of shaking, add physiological salt solution to facilitate reading. The Hipple pipetting apparatus, used in the Kahn test, and set to deliver 0.5 c.c. of saline is convenient for large series of tests.

Reading the results—Read the reactions immediately after adding saline. Record each tube as —, ±, +, ++, +++ or ++++, according to the degree of agglutination. In determination of a titer, ++ is the lowest reading to be considered as an end point.

Interpretation of results—Since in the literature agglutination titers are apt to be expressed in terms of the usual 1 c.c. test, it is important to reduce the quantities of reagents used in the two tests to equivalent terms.

In the 1 c.c. test a culture suspension of about 4 billion per c.c. is required and 0.5 c.c. of this is mixed with 0.5 c.c. of diluted serum. In the 0.2 c.c. rapid test, 0.1 c.c. of a 20 billion per c.c. suspension is mixed with 0.1 c.c. of serum. That is, in testing any particular serum dilution, one-fifth as much serum is used in the rapid test as is employed in the 1 c.c. test with the same dose of antigen. This means that on the basis of the actual amount of serum present in the dilution being tested, any particular final dilution in the rapid test is equivalent to 5 times that final dilution in the other test. For example: a series of serum dilutions 1:10 to 1:2,500 in the rapid test gives a series of final dilutions 1:20 to 1:5,000, which corresponds to a series of final dilutions in the 1 c.c. test of 1:100 to 1:25,000.

A CONVENIENT DILUTION SCHEME

		To Make Serum Dilution		
Tube No.	*Serum Dil. Required*	*Serum Dil. to Be Used*	*Serum c.c.*	*Saline c.c.*
1	1:10	undiluted	0.3	2.7
2	1:50	1:10	1.0	4.0
3	1:100	1:25	2.5	2.5
4	1:250	1.100	1.0	1.5
5	1:500	1:100	0.5	2.0
6	1:750	1:100	0.5	3.25
7	1:1,000	1:100	0.7	6.3
8	1:1,500	1:1,000	2.0	1.0
9	1:2,000	1:1,000	1.0	1.0
10	1:2,500	1:1,000	1.0	1.5

Reactions in animals—For reports of transmission of pertussis to monkeys by the injection of *B. pertussis* cultures see references 15, 16, and 17. In certain other animals, characteristic reactions follow injection of the culture and constitute helpful criteria in the study of *B. pertussis*.

A *skin reaction* is produced in rabbits and guinea pigs by the intracutaneous injection of a living suspension of *B. pertussis* Phase I. Within a few hours after injection there is an ischemic indurated area at the site of injection. By 24 hours a purplish center appears, surrounded by an

ischemic ring and beyond that, the outer part of the indurated zone appears inflamed and may show an arborization of capillaries. The central zone develops into a definite dark purple necrotic area by the end of 48 hours. After a few days, depending upon the intensity of the reaction, a scab takes the place of the purple zone, and later a scar indicates the site of inoculation. A dose of 0.1 c.c. of a 1 billion per c.c. suspension gives a reaction about 1 cm. in diameter.

Intraperitoneal injection of mice and guinea pigs with a suitable dose of *B. pertussis* Phase I is followed by death and characteristic gross pathology at autopsy. The killing dose shows considerable variation with individual animals. Usually a dose of 1 c.c. of a 5 billion per c.c. suspension kills a mouse within 72 hours. Twice this dose is usually required for guinea pigs. At autopsy there is observed a more or less extensive hemorrhagic area in the peritoneum at the site of injection, and occasionally an area of necrosis in the skin. The peritoneal fluid is increased—markedly so in the guinea pig. Frequently all organs and membranes are covered with a sticky mucoid exudate. Grossly, heart, lungs, liver and spleen show no changes. There is marked congestion around the reproductive organs. *B. pertussis* may be recovered with ease from the peritoneal fluid. Cultures from the heart's blood of the mice usually show *B. pertussis*.

B. PERTUSSIS VACCINE

CHOICE OF CULTURES

For each lot of vaccine, select several Phase I pertussis cultures which have been kept only on Bordet-Gengou medium containing at least 15 per cent blood. Just prior to their use, the cultures should be checked for Phase I characteristics [11]: typical colony appearance on Bordet-Gengou medium, including hemolysis of red cells; typical morphology and staining reactions; agglutination with Phase I antiserum; pathogenicity for mice; and skin reaction of hemorrhagic necrosis in the rabbit.

PREPARATION OF VACCINE[11, 12, 13]

B. pertussis vaccine medium—Use the cough plate medium previously described.

Inoculation of the medium—Prepare seed flasks by inoculating 500 c.c. French square bottles, each with 3 c.c. of a 10 billion per c.c. suspension in broth or salt solution of a 48 to 72 hour growth of *B. pertussis*. If larger flasks or bottles are used, vary the inoculum accordingly. Tilt the bottles until the entire surface is covered with the inoculum. After the seed flasks have incubated for 48 to 72 hours, suspend the growth in broth or salt solution and check for purity by Gram-stained preparation. Using the seed suspension, inoculate 1,000 or 500 c.c. bottles, 3 c.c. per 500 c.c. bottle. Twenty-five to 30 bottles make a reasonable number for one planting and one 500 c.c. seed bottle will afford sufficient inoculum for 6 French squares of 500 c.c. capacity.

Incubation—Incubate at 37° C. for 72 hours.

Harvesting—Discard any obviously contaminated bottles before beginning harvest. Wash off the growth on the surface of the medium with physiological salt solution using 3 or 4 c.c. per bottle. To loosen the growth, use sterile glass rods bent to reach the corners of the bottles. Make Gram-stained preparations from each bottle and examine for purity of the growth. Discard or study further by sub-culture any bottles suspected of contamination. Pool the suspensions from the remaining bottles. Wash off the residuum of growth with an additional 2 or 3 c.c. of salt solution. For 1 liter of vaccine,

about 50 bottles of 500 c.c. capacity are required.

Washing the suspension and adding the killing agent—By the addition of salt solution, adjust the pooled suspension to compare roughly with the turbidity of a known 10 billion suspension. Centrifugate in 250 c.c. centrifuge bottles for 1 hour, or until the supernatant is fairly clear. Discard the supernatant and resuspend the sediment in saline containing merthiolate 1:10,000 or phenol 0.5 per cent. The volume of this suspension should be somewhat less than that required for a 10 billion suspension to allow for dilution during standardization.

Filtering—Using a cotton and gauze filter (described under the agglutination technic), fitted into the mouth of a flask, filter the suspension to remove particles of medium and insure a smooth, even product. Wash the filter with about 10 c.c. saline to reduce loss.

Killing the organisms—Allow the suspension which contains merthiolate 1:10,000 or 0.5 per cent phenol to remain at cold room temperature for at least 1 week. Shake several times daily.

Sterility and purity tests—After the period in the cold room spread 0.1 c.c. on a Bordet-Gengou plate streaking out on half the plate. Inoculate fermentation tubes containing 25 c.c. of dextrose broth with 0.5 c.c. and 0.2 c.c. respectively. Incubate at 37° C. for 5 days.

Make Gram-stained preparations and examine for purity of the suspensions.

Standardization of turbidity—Remove 5 c.c. of the suspension from the flask and compare the turbidity with that of a known 10 billion suspension. See "Turbidity Standards" below. If the suspension to be standardized is markedly denser than the standard, dilute the entire lot to approximately 10 billion by the addition of salt solution plus merthiolate 1:10,000. Make 1:2, 1:4, and 1:5 dilutions of the adjusted suspension in vials of the same diameter as the standards and compare with the 5, 2.5, and 2 billion standards respectively. Slight differences in turbidity can be more easily detected if a printed sheet is held behind the vials, and the suspensions examined against a bright light. Dilute the lot as indicated by these comparisons, and re-check the final suspension with a second series of dilutions.

Turbidity standards—Prepare a suspension of *B. pertussis* as for a vaccine. Adjust to 10 billion per c.c. by a series of direct counts in a Petroff Hauser chamber. Check this suspension by a Hopkins tube determination as follows:

Place 5 c.c. of the suspension in a Hopkins tube and centrifugate at 2,800 r.p.m. for 30 minutes. At this time the supernatant should be clear and the organisms packed in the narrow graduated portion of the tube. If this has not occurred, centrifugate for an additional 10 minutes. Determine the amount of packed organisms in the tube as indicated by the graduations. If the two methods check, the sediment will represent 0.3 per cent of the volume. Occasionally a suspension is encountered which does not pack well in a Hopkins tube. Such a suspension should not be chosen for use as a standard.

Make 1:2, 1:4, and 1:5 dilutions of the 10 billion suspension, corresponding to 5, 2.5, and 2 billion per c.c. respectively. Seal 5 c.c. amounts of these standard suspensions—four including the 10 billion—in vials. They will keep for an indefinite period.

Filling the vials—Dispense the vaccine as desired. For individual injections, 1.5 c.c. quantities in 2 c.c. ampules are convenient; for clinic use, larger quantities are more satisfactory.

TEST OF THE FINAL PRODUCT

Sterility and purity—Test sterility in accordance with the methods outlined by the U. S. Public Health Service for the testing of biological products. In addition, from each vial tested, plate 0.1 c.c. amounts of the vaccine on blood agar and pertussis vaccine medium, and observe daily for 7 days.

Antigenicity—Test the *agglutinability* of the vaccine with a Phase I antiserum which has an equivalent titer of at least 1:10,000. The vaccine should be agglutinated approximately to the titer of the serum. Test for *agglutinin production* in the rabbit by injecting 0.2 c.c., 0.4 c.c., and 0.8 c.c. respectively per kg. weight intravenously every 3rd or 4th day and testing on the 7th day after the last injection. If the equivalent titer is not at least 1:10,000 make a fourth injection of 0.8 c.c. per kg. rabbit weight and test again after 7 days.

Safety tests—Inoculate intraperitoneally 3 guinea pigs weighing about 300 gm. with 0.5 c.c., 1.0 c.c., and 1.5 c.c. respectively. Observe daily recording loss of weight and any symptoms of toxicity. All animals should live and should regain their original weight by the end of 2 weeks.

RELEASE OF VACCINE

Release a lot of vaccine only when tests of the final product show it to be sterile, pure, antigenic and safe.

GEORGE MACL. LAWSON

Methods in Health Education*

FOLLOWING the 1934 Annual Meeting, the *Chairman*, Marjorie Delavan, appointed a Committee on Methods in Health Education.

The work of the committee has been largely conducted by correspondence except for one meeting of 3 members at Saranac Lake in June, 1935, and conferences among members as opportunity permitted.

1. Consideration has been given to the objectives of the Section, of meetings, and of the health education movement. It is believed that an attempt should be made to formulate more fully definitions and perhaps criteria of standards of health education, and of relationships. In this regard, definitions prepared by the American Physical Education Association should be studied. (See December, 1934, *Journal of Health and Physical Education.*)

Contact should be established with the sub-committee of the Committee on Professional Education dealing with the problem of health training for health educators. (Sundwall, Shepard, Connolly, Edna Gerken, and Turner.)

2. From the viewpoint of our obligation to the health education movement, we may regard our meetings:

(a) As a place for presentation and discussion of tried (but not established) procedures and of established procedures, both as regards procedures in health education and in the fields of other sections which have a bearing on health education.

(b) As a place for expounding new conceptions which seem worthy of consideration. Ultimately there might be established a body of fact and experience for guiding principles and practices as a result of the accumulation of discussions over a period of years.

From the viewpoint of our obligation to the members, we might consider for meetings:

(a) Some definite didactic presentations under a leader who is a real teacher (the material in outline form to be given to the audience).

(b) Some forum and symposium meetings.

3. Consideration should be given to the desirability of preparing a manual of methods. Is it feasible to compile elementary methods in health education which would aim to be as specific as the directions for the standard methods of water analysis or the methods for record keeping (Walker and Randolph)? How inclusive can these methods be regarding health education in schools? Can a beginning be made in the formulation of a local publicity program for a health department? Could two or three subjects be selected for study the first year, with a referee appointed for each subject as was done by the laboratory section for the Committee on Standard Methods? For those who may argue that such crystallization of practice would result in stagnation, we need only point to the *Appraisal Forms* which have been revised from time to time as experience dictated.

* Progress Report of the Committee of the Public Health Education Section.

If the Section contains a large representation of health education teachers, a sub-committee from this group might formulate this phase of the Section program.

The Public Health Education Section should be the group to give positive and tangible suggestions for the promotion of health education in various types of communities.

More specifically, one member of the committee, Miss Nickerson, has summarized some of our obligations as a section as follows:

1. To professional workers

(a) Point out their potentialities in health education—facts that should be given to the public—newspaper publicity, how to detect a news story and write it up—use of statistics to show progress, etc.

(b) Place accepted technics and methods at their disposal, and assist them in making practical use of them.

(c) Teach them the right psychological approach so that groups in their community differing widely as to race, economic level, and intellect may receive health information in terms they can understand.

(d) Help them to coördinate their work with others toward a more complete health program in the community.

(e) Show them how to evaluate their results by the use of graphic methods.

(f) Help them to adapt their special technical information to practical use.

2. To schools

(a) Keep them well informed on authoritative scientific facts on health and disease.

(b) Point out special methods for presenting these.

(c) Place the best source material at their disposal.

To this end, our Section has a duty to its members

(a) To develop standards in health education.

(b) To put its stamp of approval on and present accepted technics and methods that are known to bring the best results.

(c) Teach them to look for results by way of graphic illustrations (it might be well to have a whole session on graphs and charts, how to make them, how to read them—their usefulness, etc.).

The committee consists of the following members of the Section: Homer N. Calver, Mary P. Connolly, Elizabeth Nickerson, Evart G. Routzahn, W. P. Shepard, and Marjorie Delavan, *ex-officio*.

IRA V. HISCOCK, *Chairman*

Bathing Places*

THIS committee has been asked to review the comprehensive reports of the former committee assigned to a study of this subject and present a report to both of our associations with a view to later acceptance by the Committee on Research and Standards of the American Public Health Association. The excellent pioneering reports prepared in 1925 and 1927 by the former committee headed by Stephen DeM. Gage have been used as a guide in swimming pool sanitation since they were published. In view of the completeness of these former reports, the present committee's report is to a considerable measure composed of the older reports. There are, however, some additions and modifications submitted, dealing largely with the following subjects: outdoor bathing places; cross-connections in swimming pools; streptococci tests; residual chlorine tests; foot infections; and bathing loads. Some of the discussion on these subjects is taken from the 1930 and 1932 reports of the Joint Committee. Where particular subjects are presented verbatim from the 1927 committee report (published in the February, 1928, issue of the *American Journal of Public Health*), the heading is marked with an asterisk. The same numbers are given to various sections as are in the 1927 report. This manner of presentation would seem to offer a more useful report than would a report whose reading is interpolated with comments on the older reports. It should be understood that the bulk of this report as to swimming pools represents the work of Mr. Gage, *Chairman,* and the other members of his former committees, to whom great credit should be given. No attempt has been made to revise the earlier reports except where changes were considered to be of importance.

Extent and Prevalence of Disease Transmission by Bathing Waters—This subject might be divided into two categories: those diseases which might be spread in relatively small swimming pools where the danger of transmission is from one bather to another, assuming a safe source of water supply, and those diseases which might be caused at outdoor bathing places where there are also the dangers from waters polluted by sewage from public sewerage systems and other extraneous sources. Another distinction might be drawn as to the types of possible diseases: whether eye, ear, nose and throat infections, or skin infections such as ringworm, eczema, scabies, etc., or venereal infections, or gastrointestinal disorders.

In 1921 a committee of the American Public Health Association attempted to assemble data on the subject of spread of disease from bathing waters by sending out 2,000 questionnaires to physicians and health officers, of which 627 were answered. The replies indicated suspicions that most of the diseases to which man is susceptible may have been caused by contaminated bathing water or insanitary bathing place appurtenances. Despite these replies, it must be admitted that there is a great

* Progress Report of the Joint Committee on Bathing Places of the Conference of State Sanitary Engineers and the Public Health Engineering Section of the American Public Health Association.

dearth of epidemiological information as to just what sickness is caused by bathing in polluted water.

Conditions pertaining to bathing waters are decidedly different from those surrounding public drinking water supplies. Many persons swallow little or no water during bathing—particularly is this true of salt water—and there is fairly rapid change of water at the majority of bathing places. These considerations tend to promote likelihood of occurrence of sporadic cases of such diseases as typhoid fever among bathers as against epidemics such as may occur with polluted drinking water supplies.

Considerable interest has been evidenced by many public health workers in the possibilities of spread of skin infections from bathing. Some cases of skin eruptions on the bodies of bathers have been reported. Some investigators have concluded that a skin infection designated as "Schistosome dermatitis" has affected bathers in the waters of lakes, rivers, ponds, or beach pools which support snails. The causative agent is said to be the *cercaria,* free swimming larval stage of certain parasitic worms, of the family *Schistosomatidae.* Unfortunately it is a fact that little is known as to the exact manner of spread of many skin infections—whether the infection is spread by the use of bathing place appurtenances such as walkways, common towels, suits, or drinking cups, or by other contacts such as might occur on a public playground, or whether the water has acted simply as a vehicle of transmission of disease germs from one bather to another, or whether the infection has been from bodily excretions present in the water.

Eye, ear, nose and throat infections are reported. Some of these might be due to lowering of resistance from chills; water may wash away protective mucous discharges containing antibodies, leaving the affected parts susceptible; harmful organisms already present in the body may be washed further into the ear and nasal passages during bathing; or excessive amounts of chemicals used for water purification may cause inflammation of mucous membrane and irritation of the skin. These are all possibilities aside from any harmful infections in the water.

The summary of the replies in the 1921 report when considered in the light of known epidemiological evidence, leaves this committee unconvinced that bathing places are a *major* public health problem even though bathing place sanitation, because of the health considerations involved, should be under careful surveillance of the public health authorities, and proper sanitary control of bathing places should be exercised. Indeed, this report is prepared for that particular purpose. It is realized that new epidemiological evidence may develop. It is agreed that common sense public health programs must recognize that bathing in polluted water is a potential danger, that insanitary conditions surrounding public bathing places are a hazard, and that common decency as well as health considerations dictate that reasonable steps should be taken to secure bathing in clean environments.

These conclusions are stated as an answer to a growing demand that this committee or some other group of public health workers propose a rigorous bacteriological or other standard, whereby bathing in certain outdoor bathing waters should be condemned from a public health standpoint. There is submitted in this report a proposed method of intelligent sanitary classification of outdoor bathing places with the inauguration of promotional educational programs to provide safer and more decent conditions as against extensive arbitrary programs of bathing place condemnation, and the recommenda-

tions of the 1927 committee toward provision of what are considered to be readily attainable and necessary sanitary precautions for swimming pools are also affirmed.

Drowning and Other Accidents at Bathing Places—This report includes various recommendations of the former committee as to safeguards against drowning and other accidents at bathing places, particularly at swimming pools. These safeguards should receive consideration from health workers.

I. *Classification of Bathing Places*

*A.

*B.

II. *General Principles of Bathing Place Sanitation*

*A.

*B.

*C.

*D.

*E.

*F.

III. *Bathing Beaches*

This subject is discussed in Sections XXIX to XXXIV of this report at considerably greater length than in the 1927 report.

SWIMMING POOLS

IV. *Location and Layout of Pools*

*A.

*B.

*C.

*D.

*E.

F. At indoor pools where chlorine disinfection is to be used it is recommended that the chlorine apparatus be so located as to be readily observed.

V. *Design and Construction Features*

*A.

*B.

*C.

*D.

*E.

*F.

*G.

*H.

I. Pool Lining. Including bottom and sides up to runways lining must be of white or light color material and present a smooth finished surface without cracks or joints. All corners must be rounded. Tile or glazed brick lining is recommended for all indoor pools and for small outdoor pools. White cement smoothly finished is satisfactory for large outdoor pools. Dirt does not show on asphalt or other similar dark material and such materials are not suitable for pool lining. Sand or earth bottoms cannot be kept clean and are not recommended for pools.

*J.

VI. *Proportioning Pool Area to Expected Load*

*A.

*B.

*C.

*D.

VII. *Inlets and Outlets*

*A.

*B.

C. Proper pipe connections must be provided in recirculation pools to permit water being drained to the sewer as well as to recirculation pumps. No direct connections to sewers should be permitted and all pool drains to sewers should be broken at a point where any sewage which may back up from the sewer will overflow to waste instead of being permitted to reach the pool. Pumping of pool drainage to an elevation above any possible sewer backing may in some cases be needed.

D. Inlets for fresh or re-purified water should be located to produce so far as possible uniform circulation of water throughout the entire pool. In semi-artificial pools of irregular shape a careful study should be made of probable circulation currents, and inlets should be located and spaced to provide as complete circulation as possible. Inlets from the circulation system should be submerged to reduce escape of chlorine odors. Where water from the public water system is added to the pool, cross-connections between the public water system and the swimming pool water should be eliminated by pumping make-up water from a pump suction well or admitting water to the pool above the overflow elevation of the pool. It is recognized that the avoidance of cross-connections in this manner may require the installation of a separate heater on the line supplying make-up water—particularly where large amounts of make-up water are added.

*E.

F. (Same as "G" in old report.)

G. (Same as "H" in old report except that words "cross-connections" in third sentence are changed to "connections.")

VIII. *Scum Gutters*

*A.

*B.

*C.

IX. *Steps, Ladders, and Step Holes*

*A.

*B.

*C.

X. *Runways or Sidewalks*

*A.

*B.

*C.

*D.

XI. **Visitors' Galleries*

XII. *Dressing Rooms*

*A.

*B.

*C.

*D.

E. All dressing rooms and appurtenances must be kept clean at all times. The use of an insecticide spray for lockers and of a disinfectant on floors, walls, and seats at frequent intervals is recommended. A 0.3 to 0.6 per cent solution of available chlorine is suggested as a disinfectant, to prevent the spread of foot infections. Foot tubs without proper disinfectant solution should be prohibited.

XIII. *Showers, Toilets, Lavatories*

A. Adequate shower bath facilities with hot and cold water must be provided at all artificial pools. The minimum number of showers provided should be in the proportion of one for each 40 bathers expected at time of maximum load, in the case of continuous bathing. For bathing by classes, as at schools, the number of showers may be taken as one-third the number of pupils in the maximum class.

*B.

*C.

*D.

*E.

F. Water flush toilets should be provided wherever possible. All toilets should be properly maintained.

*G.

H. The use of solutions containing 0.3 to 0.6 per cent of available chlorine has been found of value as a foot wash for the prevention of skin infections. At many swimming pools, bathers are required to rinse their feet in such a solution before entering the pools. Many authorities consider it preferable to place the foot bath at the exit from the showers to the dressing rooms so as to spread the chlorine over the dressing room floor and increase the time of contact. In some cases, 15 per cent sodium thiosulphate solutions have been used with success as a preventive foot wash but in one large city poor results with this chemical have been reported. One reason attributed to lack of success with sodium thiosulphate is failure to employ freshly made up solutions using a good grade of chemical. Sodium thiosulphate is a reducing agent and will reduce the available chlorine in the pool if bathers use it in a foot bath before entering the pool so that its use should be limited to bathers leaving the pool.

XIV. *Lighting, Ventilation and Heating*

*A.

*B.

*C.

*D.

*E.

F. All heating units shall be isolated or protected from contact with bathers to prevent injury. The heating units in dressing rooms, shower rooms, and toilets shall be capable of maintaining a temperature between 70° F. and 75° F. The pool room heating units shall be capable of maintaining a temperature between 75° F. and 82° F. Thermostatic control of the temperature is desirable.

G. The acoustical property of pool rooms has not received the attention it deserves. Designs and materials of construction, which will prevent reverberations of sound that result in confused noises, should be used. It is very important that an instructor's voice or a call for help may be clearly distinguished.

XV. *Recirculation System*

*A.

*B.

*C.

*D.

*E. (Add "below the water surface" after "Fixed pipe connections" in last sentence.)

*F. (Add "It is recommended that piping used for different purposes be painted distinguishing colors.")

*G.

H. Thermometers. At indoor pools a fixed thermometer shall be placed on the recirculation line beyond the heater and another near the outlet of the pool. At outdoor pools one thermometer is usually sufficient. Thermometers shall be accessible and have a type of scale that is easily interpreted.

I. Cross-connections. The avoidance of cross-connections on the pool piping system whereby pool water may under some conditions enter a potable water supply system which is connected either for admission of new water to the pool or for washing of filters is discussed in Sections VII D and XVII E. The possibility of polluting pool water from sewer connections is discussed in Section VII C. The dangers of cross-connections are also stressed under this heading.

XVI. *Proportioning the Water Interchange for Recirculation and Flowing Through Pools*

*A.

*B. (Change first two sentences to the following: "Gage and Bidwell have worked out the law of purification by consecutive dilution as applied to recirculation and flowing through pools and this is described by them as follows: ")

XVII. *Filtration*

*A.

*B.

*C. (Add after first sentence "Experience has shown that satisfactory results are secured when the effective size of the sand is about 0.4 to 0.5 mm. with a uniformity coefficient not exceeding 1.75. Sand should be washed free from clay, organic matter, and soluble material.")

*D.

E. Rapid filters of open gravity type must be equipped with loss of head gauges. Pressure filters must be equipped with pressure gauges, on both the inlet pipe and the outlet pipe for determination of loss of head or back pressure in the filter medium. Pressure filters should have a proper sight glass installed on the waste discharge pipe by which the operator may watch the progress of filter washing. Such glass should be readily removable for cleaning, and should be kept clean. When pressure filters are located at an elevation above the water line of the pool, each filter must be equipped with an automatic air relief valve. The arrangement and number of valves and interconnecting piping, or "valve nest," for necessary and convenient operation of rapid filters is fairly well standardized, and a discussion thereof may be omitted. It is usually desirable to have 3 or preferably 4 pressure filter units so that 1 unit can be cut out of use and washed with the filtered pool water. With 4 filter units in ordinary use, 1 filter can be washed with the use of the recirculation pump at 4 times the ordinary filtering rate. If washing with the recirculation pump is not feasible, a wash water pump of higher capacity may be installed and a suction well or small elevated feed tank, supplied from above with water from the public water system, can be used to supply water to the pump. Valved cross-connections whereby water from a potable water supply may be admitted directly to the recirculation system for the purpose of filter washing may permit pool water to gain access to the potable water supply because of leaking valves or suddenly lowered pressures. They shall not be permitted in the case of new swimming pools. In some instances, the elimination of existing cross-connections between potable water supply systems and swimming pools is difficult. Each case should be considered in the light of existing conditions, and remedies should be sought as dictated by the relative danger and the practicality of carrying out improvements. Where such cross-connections are permitted to remain in existing swimming pools, extraordinary precautions should be required to safeguard the potable water supply.

*F.

*G.

*H.

XVIII. *Disinfection*

A. From all available information, the addition of chlorine either as a gas or in a water solution by use of proper apparatus is today the most satisfactory method of pool disinfection. It is possible not only to disinfect the entire body of water in the pool completely with chlorine, but also maintain in the pool water at all times a residual amount of disinfectant to sterilize immediately any dangerous pollution disseminated by bathers. With the proper chlorine apparatus it is also possible to increase or diminish the dosage as required to compensate for variations in the bathing load. The committee recommends the use of chlorine either as a gas or in a water solution for disinfection of all pools where there is any appreciable bathing load, or where bathing suits are worn. Recent developments indicate that the use of ammonia and chlorine for swimming pool disinfection has become increasingly popular because of the more lasting qualities of the chloramines thus formed and the possibility of carrying higher disinfecting dosages without production of irritating effects from the use of large amounts of chlorine. Reports have reached the committee that much more satisfactory results from the standpoint of avoidance of loss of chlorine from disinfected swimming pool water and of less trouble with chlorine odors have been obtained by carrying high alkalinities in the water. Experiments indicate a delayed germicidal action of chlorine with high accompanying pH content of the swimming pool water, decidedly so at a pH of 7.7, similar to the delayed action with chloramine treatment, which is a factor to be considered. The fact that chloramines are decidedly slower-acting disinfectants than chlorine alone, makes it appear to the committee that chlorine is a safer disinfectant that chlorine and ammonia. Under some conditions such as in very large or outdoor pools, however, chloramine dis-

infection may produce better over-all results.

B. A possible objection to the use of chlorine for indoor pools is the chance of accidental escape of gas into the room. Modern chlorine apparatus is carefully designed and built to prevent possibility of such accidents. As a factor of safety it is advisable to install the chlorinator and chlorine containers in a special closet or room, with vents near the floor connecting with the outside air. A chlorine gas mask is a desirable safeguard to have on hand in case of accident. Such masks should be checked up occasionally to make certain that they have not decreased in effectiveness.

C. There are now on the market machines which feed hypochlorite solutions for disinfection. Chlorine compounds may be used to make up fairly stable disinfecting solutions and so long as their strength is checked by means of residual chlorine tests on the pool water, they may be very satisfactory. There are also chlorinators in use which produce chlorine by electrolytic action on sodium chloride solutions.

*D.
*E.
*F.
*G.

H. The use of ionized silver for swimming pool sterilization has been developed abroad and to a very limited extent in this country. While satisfactory bacteriological conditions have been reported in pools using such treatment, there is a question as to how rapidly this disinfectant acts on infectious material which may be discharged into the pool water by bathers. More information is needed concerning this process, pending which the committee is unable to make a definite recommendation at this time as to its use.

XXIV. *Chemical and Physical Quality of Swimming Pool Water*

A. Excess chlorine. Whenever chlorine, calcium hypochlorite, or other chlorine compounds, without the use of ammonia, are used for swimming pool disinfection, the amount of available or excess chlorine in the water at all times when the pool is in use shall not be less than 0.4 p.p.m. or more than 0.6 p.p.m. Whenever chlorine or chlorine compounds are used with ammonia, the amount of available or excess chloramine shall not be less than 0.7 p.p.m. or more than 1.0 p.p.m. Attention is directed to the possibility of interference by nitrites with the orthotolidin test, particularly when chlorine-ammonia disinfection is employed. If readings are made on the water to be tested within 5 to 10 minutes after the orthotolidin is added, and samples are kept away from the light during this period, the nitrite interference will be decidedly lessened. Standards for determining chlorine residuals shall be prepared and used according to the recommendations in *Standard Methods of Water Analysis* of the American Public Health Association. Standardized color discs and comparators may be used.

B. Acidity-Alkalinity. Whenever alum or sulphate of alumina is used during purification or repurification of swimming pool waters, the water at all times when pool is in use shall show an alkaline reaction. This means that the hydrogen ion content of the pool water shall not fall below 7.0.

*C.
*D. (Change 72° F. to 78° F.)

XXV. *Bacterial Quality of Swimming Pool Waters*

*A.
*B.
*C.

D. All chemical and bacterial analyses should be made in accordance with the pro-

cedures recommended in the *Standard Methods of Water Analysis* of the American Public Health Association in so far as these methods are applicable to swimming pool waters. In order to secure a true picture of the condition of the swimming pool water at the time of sampling, it is recommended that sodium thiosulphate be employed to neutralize the chlorine residual in the water sample bottle during transportation to the laboratory.

E. The part played by the various strains of streptococci in the respiratory diseases and their prevalence in the intestinal, buccal, and nasal discharges make the presence of streptococci in bathing waters very undesirable. Yet to eliminate them from swimming pools would mean decidedly smaller bathing loads and decided increases in chlorine residuals, either or both of which would hamper the usefulness of the pool. The committee calls attention to the fact that streptococci tests are of value in passing on the condition of swimming pool water but does not recommend any uniform standard limit for their presence.

F. 1. Preparation of bottle for sampling. All bottles of chlorinated swimming pool water shall be collected in bottles treated with sodium thiosulphate. The purpose of using water sample bottles containing sodium thiosulphate is to reduce the chlorine present in a treated water at the moment the sample is collected to prevent a continuance of the killing action of the chlorine on the bacteria while the sample is being transported to the laboratory. The bacteriological examination then shows the true sanitary quality of the water at the time the sample was collected.

2. Several procedures for preparing the bottles are presented.

For moist heat sterilization

Option 1. The sodium thiosulphate solution is prepared by dissolving 1.5 gm. of sodium thiosulphate in 100 ml. of distilled water. One-half ml. of this solution is placed in each clean bottle. (This amount has been found sufficient to reduce completely residual chlorine in an amount up to 2.0 p.p.m. in a sample of 130 ml. of water.) After the introduction of the sodium thiosulphate solution, the bottle is stoppered and capped. The bottles are then placed in an autoclave and sterilized for 15 minutes at a pressure of 20 lb. per sq. in.

Option 2. Into clean wet bottles, add approximately 0.02 to 0.05 gm. of powdered sodium thiosulphate. The amount need not be weighed. An estimated amount on the tip of a spatula is sufficiently accurate. The bottles are sterilized as in *Option 1.*

For dry heat sterilization

Into clean dry bottles is added from 0.02 to 0.05 gm. of powdered sodium thiosulphate as in A, *Option 2.* The bottles are stoppered, capped, and sterilized at 180° C. for 10 minutes. The temperature of sterilization must not approach 220° C. as sodium thiosulphate decomposes at this temperature.

G. Collection of samples. The samples should be collected by plunging the open bottle beneath the surface, sweeping the bottle forward until filled. The bottle should not be rinsed in the pool or the sodium thiosulphate will be removed. Samples should be collected only when the pool is in use and preferably during periods of heaviest bathing loads during the day.

XXVI. *Cleaning Pool*

*A.

*B.

XXVII. *Bathing Load Limits*

A. Frequency of Changing Water:

1. The total number of bathers using a recirculation type swimming pool during any bathing period shall not exceed 20 persons for each 1,000 gallons of clean water added to the pool during that period. The term "clean water" as used above may be interpreted to mean, new clean water used to refill the pool, new clean water used to replace loss by splashing or during cleaning, water taken from the pool and returned after effective filtration, or any combination of such waters. The bathing period shall be considered as the length of time the average bather stays in the pool. Under usual conditions this may be considered as 30 minutes. The pollution load in any swimming pool will not always vary in direct proportion to the number of bathers nor to the rate of change of the pool water, but will be influenced by effectiveness of filtration, types of bathing suits used, thoroughness of pre-cleansing baths, and other local conditions. Bacteriological examinations of the pool water should be the primary factor in deciding on bathing load limits for swimming pools. Under many conditions it may be found necessary to limit bathing loads still further—perhaps on a basis of applying a figure of 10 persons per 1,000 gallons of clean

water to the 30 minute bathing period as a maximum load in the pool at any one time. It is, of course, recognized that the daily turn-over ratio of pool water in recirculation type swimming pools is of importance as well as the rate of replacement of water during bathing periods, and a reasonable turn-over ratio is needed to help maintain satisfactory conditions in the pool. As stated under "Proportioning the Water Interchange for Recirculation and Flowing through Pools," a turn-over ratio of at least 2 and preferably 3 or more, for heavy bathing loads, should exist. The above figure of 20 bathers per 1,000 gallons in a 30 minute bathing period is offered on the basis of such a range of turn-over ratio. It is the opinion of the committee that with a properly maintained pool the maximum load of bathers in the pool at any one time is of more importance in arriving at safe bacteriological conditions than the total number of bathers per day although intervals when no bathers are in the pool undoubtedly aid by promoting almost complete intermittent sterilization.

2. The total number of bathers using a fill and draw swimming pool shall not exceed 1 person for each 500 gallons of water in the pool between complete changes of pool water without disinfection. Where intermittent disinfection is employed, the number of bathers using the pool will be governed by the safe limits mentioned under "Proportioning Pool Area to Expected Load," and by bacteriological analyses of the pool water. The committee does not recommend the use of fill and draw swimming pools, as stated elsewhere.

3. The total number of bathers using an outdoor pool—partly artificial and partly natural in character, dependent for circulation and replenishment upon an inflow and outflow of water from a clean stream or a well, spring or piped water supply—might be based upon the computation outlined under (1) as a maximum limit, although safe bacteriological conditions should be the principal guide. Where pre-cleansing baths are not used at such pools, reductions in bathing loads will undoubtedly be found necessary to maintain safe bacteriological conditions even with high chlorine residuals. Pre-cleansing baths should, of course, be provided at all pools.

B. Frequency of Disinfection. The committee has decided to omit a previous recommendation as to bathing load limits between successive disinfections in pools practising intermittent chlorine disinfection in view of the recommendations as to maintenance of adequate chlorine residual *at all times* the pool is in use. It is pointed out that experience indicates that far better bacteriological conditions can be maintained with continuous chlorine disinfection. Where a pool is operated with wide fluctuation in chlorine residuals, chlorine resistant organisms may develop at times when the chlorine residual content of the water is low, and it may be necessary to use very high chlorine residuals to destroy them.

C. Area Limitation. One investigator (Mallmann) has concluded that under normal pool recirculation and design conditions, a maximum bathing load limit of 1 bather per 35 to 45 sq. ft. of pool area will result in safe bacteriological conditions with adequate chlorine residuals. In the light of experience, these figures seem reasonable. This area per bather is greater than provided for under the design requirements set under "Proportioning Pool Area to Expected Load," Section VI.

XXVIII. *Operating Control*

*A.

*B. (Change last sentence to read: "Tests for excess chlorine in the water shall be made as frequently during the day as experience proves to be necessary to maintain adequate residuals.")

C. Tests for Acidity. At any pool where alum or sulphate of alumina is used or where artificial alkalinity is added to the water, the pool operator must be equipped with a hydrogen ion testing outfit and must take hydrogen ion tests on the water every day the pool is in use, and more often if necessary.

D. Operating Records. Every pool operator must be supplied with a proper notebook or with blank forms on which shall be recorded every day the number of persons using the pool, peak bathing loads handled, the volume of new water added, the temperature of the water, and the temperature of the air. Whenever a pool is used by both males and females the number of each and whether adults or children should also be recorded. At all pools where artificial circulation, filtration, or any chemical treatment is used, a full daily record must also be kept of the actual time pumps and filters are in operation, of the time each filter is washed or cleaned, of the time and amount of each chemical used or added, of the time the bottom and sides of the pool are cleaned, and the results of all hydrogen ion, excess chlorine, or other tests.

OUTDOOR BATHING PLACES

XXIX. *Definition*

Under this heading are considered bathing places along small streams, rivers, lakes, and tidal waters. Fill and draw and recirculation bathing pools readily subject to artificial purification or to constant replenishment with uncontaminated water are not included.

XXX. *Sources of Pollution*

In a swimming pool whose water is derived from a public or other supply of unquestioned quality, it may be assumed that the presence of organisms of the coli-aerogenes group indicates pollution by human sewage particles. The presence of such bacteria in outdoor bathing places, however, may be due to the wash from cultivated fields, animals, and generally harmless contamination. Routine bacteriological tests do not differentiate between harmful and harmless contamination in such cases. Harmful contamination may be caused by sewage from boats, individual dwellings, hotels, factories, or other establishments; public sewerage systems; refuse dumping; and bathers themselves.

XXXI. *Flowing-through Bathing Pools along Small Streams*

The use of small natural or dammed-up pools along small streams by large numbers of bathers is not recommended unless disinfection is provided, as discussed in the following section. Where such pools are proposed to be used, and will be dependent upon the natural stream flow for cleansing and dilution, it should be ascertained that there is a constant and appreciable overflow of water past the dam under all weather conditions when the pool is to be used. Any small pool patronized by a number of bathers is certain to show bacteriological pollution in considerable amounts unless disinfection is provided. While no specific amount of diluting water for such pools can be recommended, it is probably fair to say that less than 500 gallons per bather per day is too small a diluting volume without disinfection.

XXXII. *Disinfection of Small Flowing-through Bathing Pools*

Disinfection is desirable to counteract pollution introduced by bathers. Hypochlorite in solution or in powdered form may be added to the pool inlet or at various points over the pool area. Chlorination of the pool inlet may be continuous. Several applications of disinfectant over the pool area during the bathing period are usually preferable to one application. Even with disinfection, the same governing factors should be considered in arriving at maximum bathing loads in small outdoor pools as presented under "Swimming Pools" (Sections VI and XXVII), and also the same limits for chlorine residuals are recommended as for swimming pools. Disinfection of large bodies of water is discussed in the following section.

XXXIII. *Disinfection of Large Bodies of Water*

The disinfection of relatively large bodies of water by use of a chloro-boat, so called, has been used with apparently some success in a few scattered instances. In some locations, bathing areas several acres in area have been disinfected satisfactorily by the use of extensive piping systems along the water bottom either for distribution of chlorine disinfecting solutions or for distribution of large amounts of pumped water drawn from the bathing area and disinfected in the pump suction with chlorine or chlorine and ammonia in what is practically a recirculation system. Where such disinfection is feasible, the same contents of chlorine and chloramine residuals are recommended as have been proposed for swimming pools. Chlorine and ammonia are undoubtedly more practical of application for large outdoor bathing areas than chlorine alone due to the greater persistence of the chloramines in the water. This probably outweighs the disadvantage of the slower disinfecting action of the chloramines as compared with chlorine. While the possibilities of disinfection methods deserve consideration, unless the future brings forth further developments in the way of attempt to establish bacteriological standards for outdoor bathing places, it appears that emphasis will be laid on the reduction of pollution of outdoor bathing areas rather than on attempt to counteract such pollution by disinfection of bathing waters. The use of disinfecting agencies, however, may be developed particularly to guard against dangers from pollution by bathers themselves in those densely populated bathing areas which are not subject to major water changes through the action of tides and currents.

XXXIV. *Collection of Samples from Outdoor Bathing Places*

Analyses of samples of bathing waters intelligently interpreted are of great value but full consideration should be given to the conditions under which samples are collected and the conditions which may exist at other times. The replenishment of bathing water by stream flow, by tidal action, and by wind and temperature currents, the contamination

introduced by bathers themselves and the intermittency of various sources of sewage pollution, are all of importance. In considering dangers from sewage pollution of bathing areas, it is well to emphasize that time is a factor of great importance. The hazard from a relatively small amount of sewage pollution in close proximity to a bathing area is far greater than a large amount at a considerable distance.

XXXV. *Bacteriological Classification of Bathing Waters*

In the collection of samples from bathing waters in connection with a scheme of relative classification of bathing waters which is subsequently presented, it is suggested that in arriving at a coli-aerogenes count on samples, a simple procedure is to run 4 or 5 dilutions from 10 c.c. down on each sample, in accordance with the expected amount of pollution and to assume 1 *B. coli* originally present in the greatest dilution to give a positive test. For example, positive in 10 c.c. and 1 c.c. and negative in 0.1 and 0.01 c.c. would be called 100 *B. coli* per 100 c.c. Where so-called anomalous results are occasionally obtained such as a sample showing positive in 10 c.c., negative in 1 c.c., and positive in 0.1 c.c., it is suggested that the greatest dilution result be recessed to the next, which in the case illustrated would give 100 *B. coli* per 100 c.c. This is an arbitrary method of computation, open to some mathematical objections, but it is simple and is satisfactory for all practical purposes. On the basis of experience, where a large number of samples has been handled, presumptive tests on lactose broth may be considered sufficient evidence of the presence of *B. coli*, the resulting error as against complete confirmation according to *Standard Methods of Water Analysis* being slight.

XXXVI. *Relative Classification of Bathing Areas Recommended*

In passing on waters of outdoor bathing places, three aids are available: (1) the results of chemical analyses of the water; (2) the results of bacteriological analyses of the water; and (3) information obtained by a sanitary survey of sources of pollution, flow currents, etc. Chemical analyses may in some cases be of value but are not ordinarily delicate enough tests.

It is not considered practicable or desirable to recommend any absolute standard of safety for the waters of outdoor bathing places on any of the three above bases. The arbitrary wholesale condemnation of bathing beaches representing large capital investments is unwarranted without definite epidemiological evidence. A relative scheme of classification of outdoor bathing places appears to offer the most promising program for public health workers to follow. Due to the difference in local conditions surrounding bathing in tidal waters, large and small lakes, and large and small streams, the degrees of classification of the bathing waters in any particular region may of necessity be varied.

In one state, a classification survey of the shore waters was carried out. The entire shore line was divided into sampling stations about 1,000 ft. apart and samples for bacteriological analysis were collected in from 2 to 6 ft. of water at high, low, half ebb, and half flood tides at each station. The results were averaged and adjoining stations combined into sections on the basis of the sanitary survey information. The analytical classification for each section was made by averaging the averages for the included stations. The sections were then classified on the basis of the analyses as follows:

	Average B. Coli per 100 c.c.
Class A	0– 50
Class B	51– 500
Class C	501–1,000
Class D	over 1,000

These same sections were also classified in Classes A, B, C, and D on the basis of sanitary survey information as to sewer outlets, float studies, etc., and final classifications were based on both the analysis and sanitary survey classifications. In the sanitary survey classifications, Class A was considered good; Class D was very poor; and the two intermediate classes ranged from doubtful to poor. Close correlation was obtained between the analysis and sanitary survey classifications.

Proposed bacteriological standards by various agencies have seemed to hit mainly upon two widely divergent limits for standards of acceptability for bathing waters, one of which is 50 *B. coli* per 100 c.c. and the other of which is 1,000 *B. coli* per 100 c.c. It is perhaps reasonable to conclude that, subject to interpretation of analytical studies from proper angles, waters better than the lower limit (1,000 *B. coli* per 100 c.c.) are fairly acceptable. Both these lines of demarcation are drawn in the classification scheme just presented and the committee recommends the use of this classification scheme unless local conditions make some other classification scheme preferable. If it is desired to set up any intermediate classifications, any classification such as "A" can be broken up

into "A+" and "A—". The interpretation of areas falling into Classes B, C, and D as to whether these areas can be considered good, doubtful, poor, or very poor, must for the present be left with the interested state health department or other agency concerned. As further information is gained from the classification of areas, more definite conclusions may be reached. It is emphasized again that final classifications should not be made upon the basis of bacteriological analyses alone but should depend largely on correlative sanitary survey information. Allowances should be made and distinctions drawn as to pollution introduced by large bathing loads at outdoor bathing places and pollution derived from sewer discharges or other sources.

The committee feels that the health board or department of each state should be the guiding agency for state-wide studies of outdoor bathing areas, with the assistance of community and district health units where practicable. Information obtained as a result of classification surveys of bathing waters should be in the hands of public health workers to enable them to furnish intelligent answers to inquiries on the part of the public. While data of this type should be released advisedly so as not to cause unwarranted depreciation of property values near bathing areas, it should serve to acquaint the public with danger spots caused by uncontrolled discharge of sewage and to promote the betterment of health conditions by installation of sewage treatment where necessary for the protection of bathing waters. The recent studies and recommendations of the Tri-State Pollution Commission (New York, New Jersey, and Connecticut) point out what may be done in the way of specifying degrees of treatment for discharge of sewage into waters allocated for recreational purposes.

XXXVII. *Sanitary Appurtenances at Outdoor Bathing Places*

Attention is directed to the need for proper sanitary appurtenances at outdoor bathing places. The remarks in Sections XII and XIII under "Swimming Pools" with regard to dressing rooms, showers, toilets, and lavatory accommodations, are also pertinent as to outdoor bathing places.

NOTE: This 1935 report of the Joint Committee on Bathing Places is presented with the hope that the committee may be advised as to any proposals for alterations and additions to the report. Any such proposals will be given careful consideration and it is intended to await reception of such proposals before recommending the acceptance of the report by the Committee on Research and Standards of the American Public Health Association.

PROPOSED STANDARDS *

Bacterial Quality of Swimming Pool Waters

A. Determination of Bacteria Counts.

1. The medium used shall be nutrient agar, prepared according to *The Standard Methods of Water Analysis* of the A.P.H.A.

2. The bacteria count shall be made from plates that have been incubated at 37° C. for 24 hours.

3. Standards. Not more than 10 per cent of the samples covering any considerable period shall contain more than 200 bacteria per c.c.

B. Determination of the Colon-Aerogenes Groups.

* This report was prepared through the collaboration of the Michigan and Detroit Departments of Health and Michigan State College.

1. The method of procedure and media shall be those recommended in the *Standard Methods of Water Analysis* of the A.P.H.A.

2. The standard portion of water for this test shall be 10 c.c. and the standard sample shall consist of five standard portions of 10 c.c. each.

3. All fermentation tubes showing 10 per cent gas shall be confirmed for the coli-aerogenes group by smearing eosin-methylene blue agar plates or transplanting into 2 per cent bile brilliant green broth. Refermentation tests may be made from the eosin-methylene blue agar plates at the discretion of the analyst.

4. Standards. The average colon index for 10 or more consecutive samples shall not exceed one per 100 c.c. of water.

At least 2 samples for bacteriological test should be taken each week.

The residual chlorine test shall be made at the pool side at the time the sample is collected.

All samples shall be tested at the laboratory at the time of bacteriological analysis for residual chlorine as a check against the removal of the chlorine by the sodium thiosulphate at the time of collecting the sample.

The following facts are presented in support of the above recommendations:

Since January 1, 1933, all swimming pool water samples in Detroit have been collected in bottles containing sodium thiosulphate. A total of 11,715 such samples have been examined through August of this year. Of the 11,598 plates examined (37° C. in 24 hours on agar), 749, or 6.5 per cent, had total bacterial counts in excess of 100 per c.c., 618, or 5.3 per cent, were in excess of 200 per c.c. and 316, or 2.7 per cent, were in excess of 1,000 per c.c. Of the 58,575, 10 c.c. portions examined for *E. coli* (partially confirmed by refermentation in 2 per cent bile brilliant green broth), 1,463, or 2.5 per cent, were positive. The average index of *E. coli* was 0.25 per 100 c.c.

Factors Affecting Work Program of Municipal Public Health Engineers*

PUBLIC health officials have never before had the opportunity of obtaining for their communities the valuable and permanent benefits which now are, or may be, made available through the employment of persons on the work relief and social security programs. Where ordinarily the opportunity for study, correlation of data, and research is limited by local budgets and number of employees, there is now available as part of the federal work relief program ample funds and in many cases personnel. Not all of these benefits will come from the extension of present health departmental activities, but may accrue by the encouragement of undertakings by other governmental agencies in their respective fields. The relationship of these various activities either directly or indirectly to the conservation of public health is recognized and appreciated by the trained sanitarian, and he is therefore the logical person to act as a coördinator for the promulgation of such a program.

The public health engineer not only has an unusual opportunity to serve his community directly, but he shares a civic responsibility to see that work relief funds are expended upon projects of maximum benefit. Much valuable data are gathering dust in the archives of our health departments and other governmental agencies because of the lack of local funds and personnel to assemble and correlate them. The construction of sanitary facilities has been curtailed to a minimum because of limited budgets. There exists today an unusual opportunity for developing programs of these types which will be of permanent benefit to public health.

As an aid to public health engineers and a guide to health departments that do not have the services of an engineer, the following list of possible projects is suggested. It is understood that the health departments may not have jurisdiction over some of the activities mentioned, but it is hoped that through their influence and guidance they will be able to encourage other governmental agencies along the lines of endeavor that will bring about permanent improvements in environmental sanitation and thereby create an improvement in the public health.

Construction programs for the extension of water mains and sewers, the erection of water or sewage treatment plants, and the rehabilitation and improvement of public hospital buildings and equipment are examples of major types of improvements that will give permanent health benefits to any community. Such programs may depend upon the ability of the locality to participate in their financing. There are, however, a large number of projects which can be carried on as a part of the work relief program.

The suggested list follows: Surveys embracing such subjects as environmental sanitation, housing, industrial hygiene, faulty plumbing, noise abate-

* Progress Report of the Committee on Municipal Public Health Engineering.

ment, ventilation, air pollution, milk sanitation, bathing facilities, stream pollution, land use surveys, city planning, and provision of recreational facilities, can be conducted. Active campaigns for rat eradication, cutting and pulling of weeds, cleaning of vacant property, mosquito control, adequate dish washing and sterilization, and the demolition of buildings which are unfit for human habitation can be carried on. The assembling and correlating of data relative to nuisances, water supplies, sewers, municipal wastes, and other environmental factors can be undertaken.

In planning any type of program the sponsor is cautioned to check carefully with his local work relief agencies in order to determine that the needed personnel will be available. A program based upon the advance information of the kinds and types of personnel available is more likely to succeed than one in which an attempt is made to adapt an unsuited group to the project.

The committee believes that if these precautions are observed and the work is carried out under the direction of a competent public health engineer, lasting contributions of great value to the health of our people will be achieved through the use of facilities now available.

Public Health Aspects of Noise Abatement*

RECENT developments in the abatement of urban noise indicate that the movement is based upon the reaction of the general public to noise as a nuisance and to the desire on the part of municipal officials to abate this nuisance. Generally speaking, municipal health departments have not been active in this field, although the public usually registers complaints as to noise or other nuisances with health departments, irrespective of the provisions of local ordinances. Although some publicity campaigns have resulted from the activities of municipal health officials, nevertheless, organized noise abatement campaigns in Europe and this country are usually under the direction of noise abatement commissions especially appointed for the purpose, because of the realization by municipal authorities that noise abatement has many aspects requiring the coördination of the activities of several municipal departments. This is evident when the sources of urban noise are considered.

Noise may be classified in two groups from the standpoint of administrative procedure, namely, the noises unavoidable at present, and those noises which can be controlled or eliminated. The unavoidable noises would be the residual noises remaining even with properly controlled traffic of modern vehicles in satisfactory state of repair, the use of modern building methods, noise hoods or screens around noisy machinery, etc. Any appreciable reduction in this type of noise will have to wait upon advances in engineering design and construction, and the replacement of obsolete noisy equipment when worn out. That such advances are in progress is evidenced by the marked improvement in the modern automobile, which is surprisingly quiet when one considers the power involved. Furthermore, future developments are to be anticipated because of the active interest shown in the reduction of noise by engineers and architects stimulated by the public demand for quiet machines. In fact, the National Standards Association, representing a number of technical organizations, is coördinating the efforts of a number of committees on noise. The present activities of these committees pertain to fundamentals of acoustics, analysis of origin and magnitude of noise, and method of preventing or dampening noise. The practical results, therefore, will be the development of more quiet machinery and sound absorbing building materials, which may be used in general construction to reduce noise to a minimum.

Noises of the second group, namely those which can be avoided by an intelligent and active campaign in noise abatement, have been shown by careful investigation to emanate primarily from traffic sources, especially the operation of elevated railways, street cars, automobiles and trucks in a poor state of repair, and the unnecessary use of the automobile horn and muffler cutouts. On the other hand, many complaints are received as to the noise from the use of radios late at night, the delivery of milk in the early morning hours, and the noisy collection of ashes and garbage. Construction activities are shown to be of minor

* Report of the Committee on Noise.

importance to a municipality as a whole because of the localized nature of noises resulting from building operations, such as riveting. It is gratifying to know that the development of welding processes is likely to supersede riveting and remove this objectionable source of noise from municipalities. Probably the most important advance in the construction field, however, is in the use of sound absorbing materials to dampen unavoidable noise.

The general public is not much concerned with noise as a menace to its health, but merely as a nuisance which should be abated. A number of individuals agree with many members of the medical profession in viewing with alarm the interference of noise with sleep, and the resulting ill effects of nervous strain. The general public, therefore, will support campaigns for noise abatement whether conducted by a noise abatement commission, police departments, or municipal health departments, provided publicity precedes such campaigns.

Generally speaking, municipal health officials are not interested in the abatement of noise because of their absorption in more important public health activities, and because there are no definite data indicating the effect of urban noise upon the mortality and morbidity rates of municipalities. Furthermore, the conclusions of eminent neurologists and physiologists as to the harmful effects of noise, and the fact that there are more than 25 noisy trades where deafness is a common occurrence among the workers, apparently has not convinced many municipal health departments that noise abatement is their immediate concern. Hence the general attitude seems to be that noise abatement is a broad municipal problem with many aspects other than the protection of public health.

Existing ordinances and laws in most municipalities provide administrative procedure for the abatement of noise, provided whole-hearted support is given to the enforcement of such ordinances. Studies by the Noise Abatement Commission of New York City have indicated that the multitude of miscellaneous ordinances of any given municipality are so scattered that administration is very difficult. Furthermore, another stumbling-block in the administration of most of the existing ordinances is that they specify that those producing avoidable and prohibited noises are committing a misdemeanor which is punishable by fines of $100 to $500, or imprisonment of 6 to 12 months. This severe penalty handicaps police officers in the enforcement of petty violations of noise abatement ordinances which, nevertheless, constitute the chief source of urban noise when considered collectively. The New York City Noise Abatement Commission has recommended that the city charter be revised to permit the imposition of so-called administrative fines of $5, and similar action might be warranted in other municipalities.

The procedure under an ordinance permitting the imposition of administrative fines would be for the violator to be handed a notice of his violation by the police officer, sanitary inspector, etc., which would indicate that the violator must pay a $5 fine at the office of the collector of taxes, rather than at a police court, except in those cases when the violator protests his innocence and demands a police court hearing, in which case the usual procedure would be followed. It may be concluded from this very careful study of local procedure required in the abatement of urban noise in a large municipality, that special noise abatement ordinances will greatly facilitate the control of this problem provided the city charter permits of the procedure outlined above.

Little can be accomplished in the

abatement of urban noise unless the general public is educated in the needlessness of most noise, its ill effects, and the possibility of its abatement. It is evident, therefore, that educational campaigns should precede any serious attempt at the control of this problem. Probably the most effective campaign is to acquaint the public through the press and radio as to the effect of noise upon the general well-being of the urban population and the results of investigations as to the origin and magnitude of noise from specified sources, and as to the proposed comprehensive campaign in noise reduction, such as that in progress in New York City, and elsewhere. In this way the coöperation of the public can be secured, and the necessary information obtained as a guide to the progress of the abatement campaign.

A widespread publicity campaign of this nature, and the organization of administrative machinery employing police officers, building inspectors, sanitary inspectors, etc., can be accomplished only through the organization of noise abatement commissions or committees, with active executives to supervise the work. It appears to this committee that sanitary engineers employed by municipal health departments are especially fitted to coöperate actively with noise abatement commissions, and to serve in many cases as the executive officer. In this way the support and influence of municipal health departments can be secured without placing undue stress upon the public health aspects of noise abatement.

The committee recommends, therefore, that those interested in the abatement of urban noise proceed along broad administrative lines through the formation of noise abatement commissions. Due weight must be given to the necessity of active publicity campaigns and the correlation of the activities of many municipal departments and bureaus so that the available administrative personnel will be utilized. Unless this is done the activity will be merely the passing of a general ordinance for lackadaisical enforcement by police departments, after the original interest has waned.

It is felt that the stimulus of an active health department is required to organize such activities and to lend assistance through active coöperation on the part of municipal sanitary engineers and sanitary inspectors. In fact, municipal health departments may have to assume more detailed supervision of such activities in the smaller city through working in close coöperation with police departments. The sanitary engineer in such cases should supervise the collection of technical data and develop control procedures to be followed by the police and other municipal employees. In this way this phase of the control of the environment can be assigned its rightful place with other environmental factors subject to control by those engaged in the field of sanitation and public health.

We respectfully submit this as a final report of the committee, inasmuch as original research by the committee is not possible, thus limiting its endeavor to the appraisal of current developments. It may be anticipated, however, that a critical review of the subject at some future date may be warranted, after the practical aspects of noise abatement have justified definite administrative procedures and have indicated the place of noise abatement in the public health program.

Recent Developments in Plumbing as Related to Public Health*

OF several recent developments in the field of plumbing, the movement to investigate the health hazards in plumbing of all federal buildings appears to be one of the most significant. Another is the increasing demand for some nationally recognized authority to pass upon the merits of various plumbing fixtures from the health standpoint. The effort by plumbers to inform themselves and the public more fully, as to what is safe in design and practice, has gained momentum and greater scope, aided by their national, state, and local associations. Manufacturers have continued to improve certain fixtures, eliminating features which menace health, and to develop additional protective devices.

In the last United States Congress, Representative John D. Dingell of the 15th Michigan district introduced in the House, and Senator Royal S. Copeland of New York sponsored in the Senate, a joint resolution calling for a survey of the plumbing in all federal buildings to discover defects that might cause disease outbreaks. The resolution was passed by Congress. It now appears probable that the survey will be made under the supervision of the U. S. Public Health Service, with the aid of the Works Project Administration, starting in two cities to develop methods and determine the practicability of extending the survey to all federal buildings. This work will safeguard the health of federal employees and of the public visiting federal buildings, and set an example for owners of other buildings.

Much of the interest attaching to this survey arises from the fact that Mr. Dingell has indicated his intention to follow through, and do everything possible to assure that plumbing health hazards, when discovered in the study, will be promptly removed, and that adequate plan examination before, and supervision during, construction will be provided to prevent new hazards in government buildings.

In the correction of plumbing defects which are hazardous to health, more specific information appears to be needed upon the adequacy and dependability of various devices. This demand has been felt in several quarters and was given expression in a resolution passed at the 1935 annual meeting of the National Association of Master Plumbers.

Some thoroughly competent scientific body having national recognition among public health authorities should secure and make available the pertinent facts, and make recommendations so that a building owner, health officer, or plumber on the job will have something more than his own judgment to guide him. Many decisions relating to plumbing devices have been made by local authorities, to meet the demand for something with which to go ahead. Uniformity would be promoted and confusion minimized by a national set of standards acceptable to all concerned.

During the past year, the public health importance of plumbing has been brought before the industry as perhaps never before. The 1935 convention of the National Association of Master

---

* Progress Report of Joint Committee on Plumbing of the Conference of State Sanitary Engineers and the American Public Health Association.

Plumbers last June featured health in an outstanding way upon its program and in the exhibits. Special demonstrations of water contamination by sewage through faulty plumbing were given to groups of master plumbers from all parts of the country. These were made possible through the cooperation of the local Master Plumbers Association, the National Association, the Journeymen Plumbers Union, the manufacturers of plumbing supplies, Mayor Edward J. Kelly, Dr. Herman N. Bundesen, and other city officials of Chicago, where the convention was held. The exhibit of the Wisconsin State Board of Health here has a similar objective. The National Association of Master Plumbers has formed a Public Health Committee upon which the American Public Health Association and other organizations are represented.

Numerous state and local plumbing groups have given particular attention to the subject of water contamination, both at their meetings and in their publications, in order to spread information and stimulate interest. Likewise, the American Society of Tropical Medicine, the Pan-American Medical Association, the Conference of State and Provincial Health Authorities of North America, the American Water Works Association, the American Hospital Association, the Western Branch of the American Public Health Association, and the American Society of Sanitary Engineering, in addition to a number of state and local groups, have given some time on their programs to this subject within the past year. At the American Hospital Association meeting, the members were privileged to witness demonstrations of water contamination caused by plumbing defects through the courtesy of the Board of Education, Department of Health, and Master Plumbers Association of St. Louis.

Experimental plumbing work in many fields by universities, technical colleges, manufacturers, and health departments, or others in charge of plumbing inspection, has been continued with material contributions to the fund of knowledge. Some work relates to health and other studies to water waste, water hammer, corrosion, etc. Unfortunately, the data accumulated have in some instances not been widely broadcast as yet, though in some other cases, such as Wisconsin, valuable bulletins or articles in the trade press have appeared. Such work deserves every encouragement by public health engineers. The Plumbing and Heating Industries Bureau has aided in securing publication of important items on health factors in plumbing, especially in trade and daily papers, and in arranging radio broadcasts on this subject.

There can be reported at this time a growing recognition that it is folly to permit contamination of drinking water in a plumbing system after spending huge sums to prevent pollution at the source or to purify the water. The wide variety of uses for water in any large city, and the complexity of plumbing systems in buildings of considerable size make the safeguarding of drinking water against bacterial and protozoal infections and chemical poisons no easy task. The recent progress and the present development of widespread interest are most encouraging for the future. It is important that the further activities be properly directed, if they are to achieve their maximum usefulness. This necessitates well qualified men who possess not only technical knowledge, but plenty of good common sense.

A. E. HANSEN

Special Problems in Park Sanitation*

THE growing interest in public park areas to preserve points of natural scenic beauty and historic interest, and to furnish camp and picnic grounds for recreational use, has introduced new phases into the familiar problem of camp sanitation. The questions of sanitary practice are much the same as those encountered in tourist camps, but there is a definite difference in administrative control. The extent of the development of this type of recreational areas is evident when you consider the National Parks—51 national monuments, and the 450 state parks that have been created. The national parks extend east and west, north and south over the country, while New York and Texas head the list of state parks with 32 each; Illinois has 30; California 29; and Massachusetts has 24. The other states range from 16 parks down to a single one, while only 3 states—Delaware, Kansas, and Louisiana—do not have any.

Apparently there is need for a general policy to direct the sanitation of recreational environment. A few of the essential points that should be considered in formulating such a policy are suggested by the sub-committee in this brief preliminary report. Glancing back a few years to the early stages of general transcontinental motor vehicle travel, the free tourist camps are called to mind. Every municipality with any pretensions had one. You may remember the insanitary chaos of these vacant lot, free camps, that were established to lure the traveller to spend a few hours and dollars in roadside towns. The lessons learned at that time can well be used in formulating a policy for state and county parks.

The development of each new state or local recreational area imposes an obligation for additional paid service by the governmental body in charge. Parks of this type when established should make adequate provisions for supervision by a paid caretaker whose services will be continuous during the portions of the year the area is in use. The public when at play can scarcely be expected to have more orderly habits than when touring. The continuing success of these parks will largely depend upon their being maintained with sufficient care so that the natural charm is not marred by unsightly collections of debris. The vacationists must continue to have a feeling of unspoiled country.

In the early stages of a movement, communities are apt to be carried away with an idea, losing sight of its practical aspects. Camps in public parks may furnish pleasure for a large number of people of all ages, but they will be enjoyed only so long as they are well maintained. The number of such camps in any area is limited by the state's ability to furnish adequate supervision. Only camps should be permitted that are absolutely necessary to care for the usual holiday crowds, and new ones should not be established until there is a definite public demand.

Organization for maintenance could be modeled on the National Park Service. This may, however, be too elaborate for the less populous states. The

* Preliminary Report of the Sub-Committee on Promotion of Environmental Sanitation.

sanitation of parks and recreational areas should be planned and supervised by the engineering division of the state board of health. The actual construction work and maintenance should be under the jurisdiction of the state park board, if one exists. It may be possible in some instances to have the highway department supervise construction and maintenance. Certainly some established department must be charged with this responsibility. It is difficult to imagine how parks can long exist in active use that are not controlled by a department directly charged with their care. Concessions are a feature of many parks, and in some instances the concessionaire might be required to act as caretaker under the direction of a governmental department.

These concessions may be anything from a hot dog stand at the entrance, to a luxurious hotel, but all of them dispensing food should be regularly inspected.

A uniformity of design for structures planned is desirable, the exteriors being in keeping with the surrounding country. Sewage and garbage disposal plants must not only be planned to afford the usual protection, but they must also be inconspicuous; located where they will mar neither the view nor the pine scented air.

The Civilian Conservation Corps, the Public Works Administration, and the Federal Relief Administration have done such splendid work in developing large park and recreational areas, that it now behooves us to formulate a general policy to govern the sanitation of these areas so that the health of the people using them will be safeguarded. A few of the salient points that may be included in such regulations are listed below:

1. Do not establish a state or local park, recreational area, or camp site without providing for a caretaker.
2. Do not have more camps than are absolutely necessary to care for the usual holiday crowds. Camps should not be established until there is a definite public demand.
3. A small charge should be made to all patrons using camp grounds.
4. Each new development imposes an obligation for additional paid service.
5. There must be an adequate supply of safe, palatable water, provisions for garbage disposal, and conveniently located comfort stations.
6. Concessions should be inspected to guarantee that they are complying with sanitary regulations.
7. Swimming pools and bathing places should comply with the American Public Health Association regulations; and should have a lifeguard on duty.
8. Sanitation should be planned and supervised by the engineering division of the state board of health.
9. Construction work and maintenance should be under the jurisdiction of the state park board or a designated governmental department.

Rural Sanitation*

YOUR committee has decided that the advance made in the field of rural sanitation through the utilization of relief labor during the last 2 years is sufficiently outstanding in importance to become the subject of this report of the committee. The chairman has been instructed by the committee to present a brief résumé of accomplishments.

Community sanitation projects were developed in 24 states during the Civil Works Program. In at least 9 of these states it is understood to have been the first intensive program ever undertaken for promotion of the construction of sanitary privies. The maximum number of laborers employed at one time during the C.W.A. program was 35,000. All but 2 of the 24 states continued the program and 8 additional states instituted community sanitation projects with E.R.A. labor. In each of the 8 additional states it is also understood that the inauguration of these projects constituted the first intensive sanitary privy program undertaken.

The popularity of the program is indicated by the fact that W.P.A. community sanitation projects calling for

* New Jersey has submitted projects to W.P.A. for approval.

approximately 60,000 laborers have been approved in 39 states.

During the C.W.A. program and through June 30, 1935, the installation of 504,212 sanitary privies has been reported by state health departments. In addition, the following items have been reported: (1) septic tanks, 5,442; (2) privies repaired, 44,680. It is estimated that there will be 3,000,000 sanitary privies constructed under the W.P.A. program.

It is exceedingly fortunate that the Committee on Environmental Sanitation provided standard plans and limiting specifications in its report presented to and adopted by this body in 1932. With the standard thus provided, uniformity in sanitary privy construction practice has been advanced to an extent and with a rapidity that could probably not have been accomplished in any other manner.

The education of the public in the importance of the sanitary disposal of excreta has been advanced many years in this short period. The interest of public health officials, and engineers in particular, has been greatly increased in rural sanitation. In all, approximately 3,000 persons have been engaged in the promotion and supervision of the program. Fully 500 of this number have been engineers. It is believed that the extent to which engineers have participated in the program accounts for the high quality of work accomplished and the advances that have been made in perfecting details of construction.

Shellfish*

LAST year we suggested that the Laboratory Section assist the Public Health Engineering Section in improving methods for the bacteriological examination of shellfish and that such methods include the examination of the entire shell contents. Some of the members of our committee and some of the members of the Laboratory Section committee have done some experimental work during the year employing a modified Eijkman method in an endeavor to find a method of examination which would report only the presence of those organisms in shellfish which were of true fecal origin.

The development of such a method, in our present state of knowledge, would help to remove suspicion from shellfish which under present methods of examination show evidence of high contamination, but which are so far removed from sources of fecal contamination that they could not possibly be affected thereby. The results of this study as carried out by members of our committee were somewhat disappointing. More detailed report on the results of this study will be found in the papers presented at the symposium on shellfish at the Milwaukee meeting of this Association this year.

The results of shellfish cleansing, particularly as applied to hard clams (*Venus mercenaria*) and soft clams (*mya arenarius*) continue to be satisfactory. More rapid progress could be made in this field—as pointed out last year—if a quick, simple, and positive method for disclosing the presence of pathogens in shellfish were available. One of the members of our committee has been engaged in making extended studies of shellfish and water scores aimed towards finding correlations with various factors that might affect the scores. The results of this study will probably be presented at a later time.

In some of the states increased activity in shellfish sanitation surveys and studies has been possible because relief funds were made available.

The further employment of funds for such purposes may make possible the collection of important data bearing upon the cleanliness of shellfish areas and the extent to which domestic and trade wastes may affect such areas.

Efforts to improve our present laboratory method of shellfish examination should be continued in the hope that a more precise and more useful method may be developed so as to make possible a more scientific sanitary control of the shellfish industry than is now possible.

* Report of the Public Health Engineering Section Committee.

The Application of Limiting Standards of Pollution of Waterways*

THERE is an increasing trend toward the establishment of standards relating to practices and procedures in practically all branches of public health and sanitation. A survey of the activities of the various committees of the Public Health Engineering and other Sections of the American Public Health Association, particularly during the past two decades, clearly shows this tendency both as regards public health administration and methods of technical control. Accordingly, in the preparation of this report of your Committee on Waterways Pollution, it was decided that a summary of the general situation as regards the establishment and application of standards of purity or cleanliness for surface waters would be desirable, with the object of stimulating additional interest in and support for such developmental work in this field as is considered practical. To accomplish this purpose, a review of literature pertinent to the subject was undertaken, such data and information as are obtainable being supplemented by that from correspondence, unpublished reports, and memoranda which were kindly made available to the committee.

It hardly needs mentioning that views on standards applying to pollution were found to be quite varied. Undoubtedly there is much to be learned, and it is an open question whether regulation of waterways pollution in some of its many aspects can or need be placed on such a definite basis as may be interpreted from the term "standards." Yet in certain phases, notably as regards limits of pollution of sources of public water supplies, there appears to be both a reasonable basis and definite need for establishing standards. What is sought in this report is simply to set forth a general survey of the situation and make suggestions relative to future procedure in formulating and putting into effect adequate standards of cleanliness for our water courses.

Many of those called upon to administer anti-pollution laws and regulations are confronted with questions as to the requirements that must be met in safeguarding public interests in our waterways. This has directed attention toward establishment of limiting degrees of pollution or standards of cleanliness for lakes, streams and tidal waters. Attempts to develop standards for general application are known to date back at least to the activities of the Royal Commissions on Rivers Pollution in England, described in reports of the First Commission in 1865, and the Second Commission in 1868, along with reports of succeeding Commissions between 1870 and 1875. In the United States attention was first given to this phase of the general problem of waterways sanitation when in 1872 the Massachusetts Board of Health began a study of sewage disposal and stream pollution in that state, leading to the well known series of investigations at the Lawrence Experiment Station.

---

* Progress Report of the Committee on Waterways Pollution of the Public Health Engineering Section.

Since these pioneering efforts to arrive at an understanding of the technical aspects of water pollution and its control, much thought has been given by various authorities to this question of standards. The literature on sanitation includes numerous references covering standards that have been established or proposed for either local or general application in connection with waterways pollution. The underlying fault or shortcoming of a number of those adopted or advocated in the past has been the lack of a sufficiently comprehensive background of properly coordinated scientific information or facts to support the standards if the matter came to a test in the courts or otherwise. The situation is very well expressed in a report for 1934 [1] of the Committee on Research of the Federation of Sewage Works Associations, as follows:

The late Professor William T. Sedgwick was fond of describing standards in sanitation as "devices to save lazy minds the trouble of thinking," which well describes the situation of his day, when a standard was generally no better than a pure guess by one worker easily seized upon, quoted and requoted by others until it assumed the semblance of authority. Something of this same method still remains in certain fields of modern sanitation, but with the development of standards committees in our great national organizations and the consequent critical discussion of current methods, together with the accumulation of scientific data upon which to base these discussions, and a formulation of a joint opinion, standards in the true sense of general agreement of opinion by expert and experienced technicians, are assuming an increasingly important rôle.

Broadly classified, the standards applying to waterways pollution set forth in the literature could be included under one or more of the following headings: those specifying—

1. Certain characteristics for sewage and other effluents that may be permitted to discharge into water courses
2. Dilutions necessary in receiving bodies of water
3. Limiting degrees of water degradation, governed by uses made of the waterways, and defined in units of readily determinable physical, chemical, biological, and bacteriological qualities of the waters

The earlier standards, such as set forth in the reports of the British Royal Commissions on Sewage Disposal and as formulated by Hering, Stearns, Hazen, Goodnough, and others, in specifying the number of cubic feet per second of stream flow required for the inoffensive disposal of sewage contributed per 1,000 population, can be grouped largely under the first two headings. It is evident that these standards were developed with the prevention of nuisances as the primary purpose, rather than the safeguarding of public water supplies.

Developments in recent years would indicate that the trend in standards of waterways pollution is toward the third classification, where all or major uses of the waters are considered. Based largely upon the comprehensive studies of the U. S. Public Health Service, there is now a tendency toward definitely limiting the *B. coli* content allowable in waters usable as sources of public water supply. For instance Jordan [2] states:

The approach to a density limit of sewage organisms in a raw water is definite. Various expressions of this have been made, but none so definite as that of Streeter at the close of his long series of studies of performance of purification plants. Whether or not one agrees with the reasoning, he at least must defend against the indictment the use of any raw water whose average *B. coli* content exceeds 5,000 per 100 ml. It is reasonable to expect that in any future revision, the Treasury Standard limitations will not only be set as they are now upon the quality of finished waters, but also may be suggested as to limiting average *B. coli* index of raw waters.

Two types of standards (1 and 3 of the foregoing classification) are included in the interstate compact proposed by the Tri-State Treaty Com-

mission[3] of New York, New Jersey, and Connecticut for the abatement of pollution of the harbor and coastal waters of the Metropolitan Area of New York City. This included a recommendation that the waters be divided into two general classes, namely, Class A waters, which are used primarily for recreation, shellfish, and culture of fish life; and Class B waters, which are not expected to be used for such recreational and shellfish propagation purposes. The proposed compact also provided that all sewage tributary to Class A waters shall be subjected to a degree of treatment sufficient to remove all floating solids and at least 60 per cent of the suspended solids to effect a reduction of organisms of the *B. coli* group so that the probable number of such organisms shall not exceed 1 per c.c. in more than 50 per cent of the samples of effluent tested by the presumptive method, and to maintain in the general vicinity of the point of discharge at a depth of about 5 feet below the surface of the water a dissolved oxygen content of not less than 50 per cent saturation during any week of the year. Under Class B waters the specified treatment requirements for sewage were such as to secure removal of all floating solids, at least 10 per cent of the suspended solids, avoid formation of sludge banks, and effect a reduction in the oxygen demand of the sewage sufficient to maintain in the general vicinity of the point of discharge a dissolved oxygen content of not less than 30 per cent saturation during any week of the year.

An excellent review of the trends in water pollution standards has been prepared by Streeter,[4] in which he concisely summarizes the present situation as follows:

The older standards, based on fixed dilution ratios, are being superseded by more definite specifications of certain indicators of relative cleanliness, such as bacterial content, dissolved oxygen, oxygen demand, and known toxic chemical substances. Where the public health is involved, limiting standards of bacterial quality, notably with respect to the density of organisms of the *B. coli* group, are becoming of primary importance, though in some instances limitation of chemically toxic substances is almost equally significant. At the present writing a reasonably firm empirical basis exists for the formulation of working standards of pollution for practically all waterways in this country used as sources of public water supply. This should be done in the near future, so as to coördinate efforts in the various states toward a rational and uniform policy in dealing with this problem, especially in its interstate aspects.

A fairly good basis also now exists for the formulation of tentative standards of pollution for shellfish growing areas, and for natural bodies of water utilized for public bathing. In the latter case, however, caution will be necessary in attempting to meet a bathing water standard in some natural waterways subject to noncontrollable pollution by surface drainage water and storm sewage. In some of these instances, at least, the extent of dilution provided would not be sufficient to permit conforming to such a comparatively rigid standard, even if the effect of all the dry-weather sewage entering the waterway were to be removed through adequate treatment.

Where the public health is not involved, the minimum dissolved oxygen standard appears to be the most simple and readily applied one for general application, though a distinct trend toward oxygen "balance" criteria is apparent. Some question remains as to just where the minimum oxygen level should be placed in specific cases, with a strong tendency to fix it at not lower than 3 or 4 p.p.m. and at even higher concentrations in some cases. As organic sludge deposits are particularly harmful to fish life and tend to exert a disproportionately heavy oxygen demand on overlying bodies of water, a definite need exists for standards of sewage and industrial wastes treatment adequately stringent to result in practically eliminating these deposits from all streams and lakes.

Through an inquiry directed to chief sanitary engineers of 25 state departments of health, Streeter found that beyond the U. S. Treasury Department Standard for drinking waters, there are no standards of cleanliness for waters devoted to various uses that

are generally accepted; that where other standards are applied, except as related to limiting degrees of pollution for sources of purified water supplies, these standards are not based on systematic observational data; and that there appears to be a fairly widespread sentiment favorable to the more general use of water quality standards, if they can be based upon such scientific data as to justify their acceptance with every confidence.

Considering the varied uses of waterways, such as for public water supply, watering of stock, industrial water supply, propagation of fish, shellfish, and other aquatic life, recreational purposes, including bathing and boating, navigation, and agricultural development involving irrigation, it is apparent that there is a large task to be performed before this condition for general acceptance of standards can be met. Harmful effects of pollution pertaining to these uses must be properly evaluated and limits defined in suitable physical, chemical, biological, and bacteriological units. The relation one to the other of the various units must be more thoroughly established. This is essential to intelligent application of any general standards to waterways having more than one major use. It is evident that only through the coöperation and careful coördination of results of research conducted by sanitary engineers, laboratory workers, epidemiologists, fish culturists, and many others will it be possible to proceed satisfactorily toward the establishment on a firm scientific foundation of acceptable standards of cleanliness for lakes, streams, and tidal waters.

To facilitate carrying out the necessary research and to provide ways and means for collecting, coördinating, and disseminating the results obtained, it is considered most desirable that some definite agency of the federal government be designated and provided with adequate funds to undertake the task. That the problem is of nation-wide importance is evidenced in many ways, and is recognized in Part III of the *Report of the National Resources Board to the President*,[5] which under the heading of water planning deals with the problems of waterways pollution. As the only comprehensive studies of a scientific nature on waterways pollution performed by the federal government have been conducted by the Office of Stream Pollution Investigations of the U. S. Public Health Service, and as it is believed to be well constituted to carry out the work effectively, your Committee on Waterways Pollution recommends that this Section go on record as urging favorable consideration by the appropriate authorities to the designation of this agency as a national clearing house for research and other activities necessary in the formulation and harmonizing of standards of water quality.

DISCUSSION DEALING WITH LIMITING STANDARDS OF WATERWAYS POLLUTION

H. W. STREETER
Sanitary Engineer, U. S. Public Health Service, Cincinnati, Ohio

THE subject of limiting standards of pollution for waterways devoted to various uses has been considered for many years, dating back to the work of the Massachusetts Board of Health in the 1880's and of the British Royal Commission on Sewage Disposal in the late 90's. With the recent increase in stream pollution throughout the United States and the growing public consciousness of the problem, interest in this subject has been revived on the part of those sanitary authorities who are faced with the possible institution of extensive stream cleaning programs in the near future. Consideration of this subject by a committee of this Association is, therefore, both timely and profitable.

In connection with a survey of national water resources made during the present year by the Water Resources Section of the National Resources Board, the present situation with respect to the use of water pollution standards in this country was reviewed for the board in a special report prepared by the speaker. A canvass was made of existing practice in the application of such standards in some 25 states, representing a fair cross-section of the country. The results of this canvass, together with a review of recent literature on the subject, have been taken as the basis of the present discussion.

In a general way, the results of the canvass indicated: (1) that aside from the Treasury Department drinking water standard, no standard of quality or cleanliness for waters devoted to various uses has any widespread degree of acceptance among the several states; (2) that other standards, where applied, are diverse in their requirements and with one exception are not based on extensive or systematic observational data; and (3) that with a few exceptions there appears to be a fairly widespread sentiment favoring the more general use of water quality standards, provided that they can be based on a sufficiently firm scientific foundation to justify their general acceptance.

WATER SUPPLY STANDARDS

From a public health viewpoint, the most important phase of the subject has to do with standards of quality for public water supplies and their sources. For domestic water supplies, the present Treasury Department standard has been a widely useful criterion, despite the fact that it was originally intended for application only to drinking and culinary waters supplied by the interstate carriers. With a few minor amendments, principally those designed to eliminate and restrict certain harmful chemical substances not included in the present requirements of the Standard, it can be readily extended as a suitable criterion of safety for all public water supplies. For industrial water supplies, requirements are so variable that no general standard of quality seems to be applicable. Progress in studies of this phase of the subject is being made by the U. S. Geological Survey under the direction of Chief Chemist W. D. Collins and by a subcommittee of the National Water Resources Committee headed by S. T.

Powell, who has made a particular study of boiler waters in this connection.

The matter of limiting standards of pollution for sources of purified domestic water supplies has been studied for a number of years by the U. S. Public Health Service, in connection with its stream pollution investigations. The results of this study, which involved extensive observational surveys of over 30 municipal filtration plants and the operation of a specially constructed experimental filtration plant for about 5 years, have led to the recommendation of a definite limiting standard of pollution for raw waters requiring filtration and for waters requiring only simple chlorination.[1]

For raw waters requiring filtration, the recommended standard would provide: (1) that the average *B. coli* index, when considered over a significantly long period of time, such as a year, should in no case exceed 5,000 per 100 c.c. and (2) that the *B. coli* index on individual days should not exceed 20,000 per 100 c.c. for more than 5 per cent of the same period, in which case the limiting average index might be as high as, or something less than 5,000 per 100 c.c., according to the character of the source and variability of water taken from that source. For waters requiring only chlorination, the average *B. coli* index should not exceed 50 per 100 c.c., or a figure sufficiently lower so that an index of 400 per 100 c.c. would not be exceeded for more than 5 per cent of the time. Both of these standards are based on the assumed production of purified effluents meeting both requirements of the Treasury Department *B. coli* standard. The term "index" may refer either to the Phelps number or to the "most probable number" of *B. coli*.

The standard recommended is now being followed with various modifications by several state health departments in fixing requirements for the quality of sources of purified municipal water supplies. Incidentally, it is the only limiting criterion of water quality thus far developed, which, as far as the speaker knows, is based on extensive and systematic observational data. For general use, it should be amended so as to provide for the restriction of certain harmful and taste producing substances which cannot be effectively removed by ordinary water purification processes.

Among other water quality standards having a more or less direct bearing on the public health are those which have to do with recreational uses of waterways, such as bathing and fishing, with certain agricultural uses, notably stock watering and irrigation of food crops intended for human consumption, and with the maintenance of general cleanliness and freedom from "nuisance" in streams, which is closely related to the suitability of bordering land areas for healthful dwelling places.

In the several fields of application of these standards, wide divergences in opinion and practice are found among the various states. This is particularly true of bathing water standards, which range from a limiting *B. coli* index as low as 50 per 100 c.c. to one as high as 1,000 per 100 c.c. Minimum dissolved oxygen requirements for the maintenance of aquatic life also show quite a diversity, varying from as low as 2.0 to 5.0 p.p.m. or more. Some fish experts, notably Dr. Hubbs of Michigan, hold that no definite dissolved oxygen minimum can be set, as the killing limit varies with temperature and various constituents of sewage have different effects on fish. Hubbs expresses a preference for an oxygen reserve standard, in which a fixed excess of dissolved oxygen over oxygen demand is specified, such as, for example, 3 p.p.m.

Standards of cleanliness for waters used in agriculture have been adopted in only a few of our states, notably in California, Colorado, Maryland, and the southwestern group. For irrigation waters applied to edible vegetable crops, the most definite standard is in Colorado, where such waters must not contain more than 1,000 coli-aerogenes bacteria per 100 c.c. Opinions vary widely as to the quality requirements of waters used for stock watering. At one end of the scale is the view that domestic cattle should be served only with water fit for human consumption. At the other end is the view that harmful effects of sewage on cattle are slight unless it contains chemical poisons or affects the protein intake of food. In Maryland, sewage entering streams used for stock watering must be chlorinated.

The history of efforts to set up standards of general cleanliness for polluted bodies of water extends back over a period of more than 25 years to the formulation of the British Royal Commission standard for sewage effluents and the various dilution standards recommended for use in the United States. Among the 25 states recently canvassed, only 4 have any definite standards in this respect, though several other local standards have been proposed in recent years. Among these is the standard suggested by Howson and Burdick for the Illinois River, in which the minimum dissolved oxygen content would be not less than 3 p.p.m. nor less than the 5 day biochemical oxygen demand at 20° C. This is similar in principle to the reserve oxygen, or "fish zero" standard proposed by Hubbs. Another recent standard set up for localized application is that of the Tri-State Pollution Commission for waters bordering the greater New York metropolitan area. This standard divides the waters into two classes, A and B, with considerably higher requirements for Class A than for Class B, the former being set aside for bathing and other recreational purposes. For Class A waters, among other requirements, the *B. coli* index is limited to 50 per 100 c.c., and the dissolved oxygen minimum to 50 per cent of saturation. For Class B, the oxygen minimum may be as low as 30 per cent of saturation.

Although it is possible that no fixed standards of the kind would be generally applicable to all classes of waters, there seem to be certain basic requirements that are common to all waters where freedom from "nuisance" conditions and their utilization for recreational purposes are desired. One requirement is the removal of all, or practically all, of the settleable organic solids from sewage and industrial wastes discharged into such waters, in order to prevent the formation of sludge deposits, which are detrimental to normal stream life. It is also agreed that for the prevention of "nuisance" or other undesirable conditions, the dissolved oxygen content should not fall below a certain minimum, and a favorable "oxygen balance" should be maintained. The precise location of these optima to meet the conditions of various uses of waterways still remain to be defined, in so far as their general acceptability is concerned.

In addition to these basic requirements, are others to be considered, notably with respect to the freedom of waters from biological growths resulting from the discharge of sewage and sewage effluents, the presence of certain toxic substances detrimental to maintaining a normal biological equilibrium in natural bodies of water and possible effects of oils and tarry substances on the natural life and purification capacity of these waters and their normal use by riparian dwellers.

The present status of water pollu-

tion standards and their application in this country may be summed up very briefly as follows: The use of such standards has been limited thus far to a comparatively few states and has been marked by a general lack of agreement as to their specific requirements for particular kinds of water utilization. As the result of the virtually unrestricted pollution of our waterway systems which has been permitted in the past, conditions in many of these waterways have become so serious that demands for their relief are becoming increasingly widespread and insistent. If these measures are to be both effective and economical, they should be planned and executed with a view to meeting definite limiting standards of pollution, fixed according to the requirements of each major water use involved and based on a scientific study of these requirements.

At the present writing, aside from the Treasury Department drinking water standard, which has become established as a reasonably safe criterion through long and wide experience, none of the standards mentioned in connection with this discussion has at present any widespread degree of acceptability or actual use. Of these other standards, only one, so far as is known to the speaker, has been recommended as the result of any systematic and comprehensive observational study. At the same time, virtually all of these standards are of such a nature that, once established on a scientific basis, they should be capable of fairly general applicability, because they have to do with water quality requirements which are common to all individuals and practically all situations of a given class. It is hardly conceivable, for example, that safety requirements for drinking or bathing waters would vary to any appreciable extent among several groups of individuals, wherever they might be located, or that the essential subsistence requirements for given species of fish or other aquatic life would vary widely in different bodies of water.

The present need, then, seems to be that some public health research agency experienced in water pollution problems and having at its command the necessary personnel and working funds, undertake a thorough study of the limiting requirements to be met for various kinds of water use, with a view to recommending standards based on such requirements. A study of this kind, if adequately planned and financed, would reveal more definitely the stronger and weaker points of standards now in use and would inevitably lead to their improvement and adaption for wider application. This general method of approach seems to be greatly needed at present in considering the question of water pollution standards, which too often in the past have depended on individual opinions backed by inadequate supporting data. If this Section of the American Public Health Association can lend its aid toward such an effort, it will be rendering a notable service to the cause of intelligent waterways pollution control in this country. The action of your committee in bringing the matter up for discussion at this time is most commendable.

To Study Nursing Service in State Departments of Health*

THE Committee to Study Nursing Services in State Departments of Health was set up as a joint committee because the work followed a study of State Nursing Services made by the National Organization for Public Health Nursing in 1931 and also because the question involved represented the interest of both groups. A large part of the statistical service has been given by Anna Miller, of the National Organization for Public Health Nursing staff, and without such valuable help the committee could not have functioned effectively.

The committee conceived its broad purpose to be the strengthening of nursing service in state departments of health. Its more immediate objectives were defined as three:

1. Collection of facts regarding the organization functions and practices in state nursing in the several states
2. Study of the collected data
3. Interpretation of the findings to determine whether the different situations offer comparable problems which may have some solution through the formulation of fundamental principles in the organizing and functioning of state nursing services

COLLECTION OF FACTS

Facts were collected through the medium of a questionnaire which included in its scope only such items as dealt with organization, functions, and methods. This limitation as to scope seemed desirable in order not to duplicate effort, because another joint committee to study personnel practices in states had its plans well under way. The two committees cleared plans and decided to exchange information. The questionnaire of this committee was sent to the 48 states and, in addition, to the District of Columbia and to Hawaii. All but three states, Delaware, Colorado, and South Carolina, returned the questionnaires.

The information received has been tabulated and obvious inconsistencies have been checked through correspondence. The data now available are sufficiently accurate and complete for the general purposes of the committee; but if the information were to be summarized by states following the form of the National Organization for Public Health Nursing study of 1931, the summary should very obviously be submitted to each state for final checking and approval. At the present time, the committee does not believe that such a specific summary is indicated, although a comprehensive summary of the answers to each item contained in the questionnaire might easily be prepared for distribution to the states which participated in the study. Several states indicated their interest in a complete report of work in other states so identifying information may have its value.

STUDY OF DATA

The information collected was carefully studied by the separate members of the committee and finally in meeting. It is considered significant that the interest of the committee increased during the 3 hour conference which was held just before the Annual Con-

* Report of the Joint Committee of the National Organization for Public Health Nursing and the American Public Health Association.

ference of the American Public Health Association in Milwaukee. The committee was unanimous in its belief that the study offered many possibilities which had not been thoroughly sounded. Sufficient refinement of the tabulation has not been made to include in this report a summary of the statistical information upon which the tentative conclusions of the committee are based. It is hoped that the following general statement will be accepted before the complete report is offered:

There are striking similarities in concept of function and in the concrete problems as outlined by the various states; on the other hand, there are wide divergencies in organization and in the methods by which similar problems are met. These factors offer great opportunity for further productive study. It is upon this tentative generalization based on the study of factual information that the committee offers its present conclusions:

1. The major problems seem to point to those of organization, budget, and personnel and are therefore administrative in character.
2. From the evidence at hand, there is a similarity in purpose in relation to public health nursing in several states to justify further study as to fundamentals in organization, functions, and methods.
3. The committee recommends the continuation of the study with the thought that the work ought to be continued in coöperation with the Nursing Committee of the Committee on Administrative Practice.

Accident Statistics

IN the absence of the Chairman, no formal report of the Committee on Accident Statistics was presented at the annual meeting in Milwaukee. The Chairman of the committee presented by letter a statement reviewing the past work of the committee, its inactivity during the past year, and a statement of possible problems that the committee should consider in the future.

It was suggested that the committee continue its previous promotion of the collection of supplemental data on fatal accidents by official departments of health and to continue its coöperation with non-official agencies such as the National Safety Council and the American Museum of Safety in the collection of accident statistics. The statement of the Chairman referred to the many agencies in the federal government that were collecting statistics on one or another kind of accidents but that no single federal agency is responsible for putting these data together. Dr. Louis I. Dublin recommended that the Vital Statistics Division of the Federal Bureau of the Census consider as one of its major responsibilities the publication of complete annual statistics of accidents. He referred to the excellent work of Dr. Earle G. Brown of Kansas in analyzing data available on fatal accidents in Kansas.

The Section referred the statement of the Chairman to the Section Council which decided to continue the committee appointing a new chairman to take the place of Dr. Fales who had requested to be relieved of the chairmanship because of lack of time to carry on the work of the committee.

Accuracy of Certified Causes of Death

THE report of the Committee on Accuracy of Certified Causes of Death and Its Relation to Mortality Statistics and to the International List was approved, in principle, by the Section on Vital Statistics of the American Public Health Association, at its meeting in Milwaukee, Wis., in October, 1935.

This report presents the committee's recommendations as to—(a) what titles of the present (Fourth) revision of the *International List of Causes of Death* should remain therein; (b) what terms should be listed under each title; (c) what terms should be transferred from one title to another. The full report was published in the *Public Health Reports*, September 13, 1935, and will appear as *Reprint No. 1706* from the *Public Health Reports*.

HAVEN EMERSON, *Chairman*

Stillbirths*

THE conclusions and recommendations of the Sub-committee on Stillbirths are offered for consideration of the Section on Vital Statistics for discussion before submission to the Committee on Research and Standards.

On approval by the latter standing committee of the Association, the Committee on Accuracy of Certified Causes of Death will represent the Association in conferences in this country and in Europe in preparation for the revision of the *International List of Causes of Death* which is planned for 1938 in Paris.

Before we can hope effectively to reduce the fetal and maternal losses, we must have adequate information with regard to the magnitude of the problem, the variations in prevalence, and the underlying fetal and maternal conditions associated with stillbirth mortality. The information is within the possibilities of statistical tabulation and analysis. Completeness of registration, comparability of original records, and uniformity in the use of terms and in registration practice are prerequisites.

Stillbirth registration is recognized as grossly incomplete in practically all sections of the country. Glaring lack of uniformity is found in the minimum period of uterogestation for which stillbirth registration is required. Variation also exists in the evidence of life used to distinguish between live and stillbirths; for although most states use the American Public Health Association rule No. 19 of Statistical Practice as amended in 1913, few have included it in recent instructions to certifying physicians. There is not in common use a list of causes, maternal and fetal, ante- and intra-partum, which lead to the occurrence of stillbirths.

To remedy these defects your committee recommends: Active stimulation of the registration of stillbirths, both as separate projects and in connection with campaigns for the improvement of registration of live births; the promotion of uniform state laws and regulations with regard to the minimum period of uterogestation to be used for recording, and the evidence of life to be used in distinguishing between live and stillbirths. Your committee also recommends the approval by the Section on Vital Statistics and by the Association, on recommendation of the Committee on Research and Standards, of a form of certificate of fetal death, and a list of terms to be used as a basis of a table of stillbirths by cause to be included in the annual report on Birth, Stillbirth, and Infant Mortality Statistics of the U. S. Bureau of the Census, and to be published by the states and by the larger cities in their annual reports. It also recommends that the *Physician's Pocket Reference* to the *International List of Causes of Death* issued by the Bureau of the Census be expanded to include a section on stillbirths which will emphasize the importance of stillbirth registration, give the definition of stillbirth, and the evidence of life to be used in distinguishing between live and stillbirths as recommended by the American Public Health Association in Rule 19, 1908,

* Report of the Sub-Committee on Stillbirths of the Committee on Accuracy of Certified Causes of Death. This report is presented for discussion prior to its adoption.

and the resolution of 1913, together with a list of fetal and maternal causes of stillbirth.

The following five matters were considered by the Sub-committee on Stillbirths to require clarification and formal agreement for purposes of public declaration of policy by the public health profession as represented in the American Public Health Association:

A. Definition of live and stillbirths
B. Elements of a uniform state law requiring the reporting of stillbirths
C. A standard certificate of stillbirth
D. A list of causes of stillbirth, whether determined in the fetus or related to conditions in the mother
E. Joint Cause Practice for the assignment of stillbirths

A.

Your committee wishes to call attention to the excellence in matter and form of the Report of a Committee on Definition of Stillbirth submitted to this Section in 1927 by Drs. Henry B. Hemenway, William H. Davis and Charles V. Chapin, which refers to correspondence in the Census Bureau by Dr. Cressy L. Wilbur in 1907, and with approval to No. 19 of Rules of Statistical Practice adopted by the Section on Vital Statistics of the A.P.H.A. in 1908, which reads as follows:

No child that shows any evidence of life after birth should be registered as a stillbirth.

In 1913 the following resolution was adopted by the Section on Vital Statistics:

Resolved, that the present Rules of Statistical Practice relating to stillbirths and premature births as adopted by the American Public Health Association in 1908, should be strictly followed by American registration offices, it being understood that the words *any evidence of life* in Rule No. 19 should include action of heart, breathing, movement of voluntary muscle.

It was further noted in this report of 1927 that,

So far as is known to the members of this committee, American statistical offices have been strictly observing this rule as amended by the resolution, except that the Province of Quebec has determined the fact of life after birth solely by the act of breathing.

The report of 1927 (Hemenway, Davis, and Chapin) considers in detail a communication from the Health Section of the League of Nations dated April 1, 1925, and refers with approval to No. 16 of the Rules of Statistical Practice (1908) which reads as follows:

Statement of viability or non-viability of an infant prematurely born shall not be considered in classifications.

The report further correctly states with admirable brevity that

The term stillbirth or deadbirth has universally been recognized as meaning dead at the moment of birth. Death means absence of life. As generally recognized the status of fetus terminates at birth, provided that the organism is alive at time of birth. Life of an animal is shown by heart beat, respiration or movement of voluntary muscle. This is general, and it applies to adults as well as to newborn children.

The report concludes with the recommendation that the existing rules of statistical practice regarding stillbirths be reaffirmed.

Rule No. 4 (4, 1908)—Stillbirths should not be included in deaths.

Rules No. 5 (5, 1908)—Children born alive and *living for any time whatever*, no matter how brief, after birth, should not be classed as stillbirths, even though reported by the attending physicians or midwives as "stillborn."

Rule No. 6 (6, 1908)—Wherever age, in days, hours or minutes, is reported for a "stillborn" child, or indicated by a difference between dates of birth and death, the registrar should secure a statement that will enable the case to be classified with certainty either as a stillbirth or as a death. If no additional information can be obtained, the statement of age should govern, and the case be compiled as a death, not as a stillbirth.

Rule No. 17 (17, 1908)—For registration purposes, stillbirths should include all children born who do not live any time whatever, no matter how brief, after birth.

UNITED STATES STANDARD CERTIFICATE OF STILLBIRTH

Definition of a stillbirth.—A stillborn child is one which shows no evidence of life after complete birth (no breathing, no action of heart, no movement of voluntary muscle). Birth is considered complete when the child is altogether (head, trunk, and extremities) outside the body of the mother even if the cord is uncut and the placenta still attached.

Why stillbirths should be registered.—Registration of all stillbirths is important: FIRST, on account of the great loss of human life occurring in the prenatal and natal periods; SECOND, on account of the relationship between fetal deaths and maternal mortality and morbidity. Although it is often impossible to determine the exact cause of fetal death, information regarding the associated conditions will lead the way to lowering the high fetal and maternal mortality. Important causes and associated conditions frequently found are shown below.

Instructions re Inq. 34. Cause of stillbirth (a) Fetal (b) Maternal.—Describe fully the conditions in the fetus and mother which were associated with the fetal death—i.e., conditions found in the fetus at the time of birth and diseases and conditions of the mother during pregnancy and labor. Indicate the condition you consider the primary cause of the fetal death. For example: The dead fetus was hydrocephalic; the mother had had a mild case of toxemia during pregnancy; the fetus would probably have been live born except for the hydrocephalus. Enter under Inq. 34: (a) Fetal—"Hydrocephalus—primary." (b) Maternal—"Toxemia."

CAUSES OF STILLBIRTH

A. CAUSES DETERMINED IN THE FETUS

1. Infection
   a. Syphilis
   b. Sepsis
   c. Other infections

2. Asphyxia
   a. Separation of placenta
   b. Abnormalities of cord
   c. Other causes of asphyxia

3. Congenital malformations
   a. Hydrocephalus
   b. Anencephalus
   c. Spina bifida and meningocele
   d. Malformations of heart
   e. Other

4. Birth injury
   a. Malpresentations
   b. Difficult labor
   c. Other causes of physical injury of the fetus

5. Other diseases or conditions affecting the fetus primarily

6. Cause unknown

B. CAUSES AND CONDITIONS IN THE MOTHER ASSOCIATED WITH THE FETAL DEATH

1. Infectious and parasitic diseases
   a. Influenza
   b. Tuberculosis
   c. Syphilis
   d. Other

2. Cancers and other tumors
   a. Malignant and other tumors of the female genital organs
   b. Malignant and other tumors of other organs

3. Rheumatic, nutritional, endocrine, and other general diseases
   a. Acute rheumatic fever
   b. Diabetes
   c. Diseases of the thyroid and parathyroid glands
   d. Other

4. Diseases of the blood and blood-making organs
   a. Pernicious anemia
   b. Other

5. Chronic poisonings and intoxications
   a. Alcoholism
   b. Lead poisonings
   c. Other

6. Diseases of the nervous system and organs of special sense
   a. Psychosis
   b. Epilepsy
   c. Other

7. Diseases of the circulatory system
   a. Diseases of heart
   b. Diseases of arteries

8. Diseases of the respiratory system
   a. Bronchitis
   b. Pneumonia
   c. Other

9. Diseases of the digestive system
   a. Diseases of liver—specify
   b. Appendicitis
   c. Hernia, intestinal obstruction
   d. Other

10. Diseases of the genitourinary system—known to have preceded pregnancy
    a. Nephritis
    b. Other

11. Diseases of pregnancy and childbirth
    a. Sepsis—observed before delivery
    b. Albuminuria, eclampsia, and pyelitis
    c. Other toxemias—specify with or without convulsions
    d. Hemorrhages, ante-and intrapartum, due to placental abnormalities and other conditions
    e. Ectopic gestation
    f. Other accidents of pregnancy and childbirth—specify

12. Operations other than for delivery—specify

13. Conditions of the bones interfering with normal labor

14. External causes
    a. Traumatism—blow, fall, shock, etc.
    b. Overwork
    c. Other—specify

15. Other diseases and conditions of the mother—specify

16. Cause unknown

U. S. GOVERNMENT PRINTING OFFICE

Rule No. 18 (18, 1908)—Birth (completion of birth) is the instant of complete separation of the entire body (not body in the restricted sense of trunk but the entire organism, including head, trunk, and limbs) of the child from the body of the mother. The umbilical cord need not be cut or the placenta detached in order to constitute complete birth for registration purposes. A child dead or dying a moment, no matter how brief, *after* birth, was a living child, and should not be registered as a stillbirth.

Rule No. 19 (19, 1908)—No child that shows any evidence of life after birth should be registered as a stillbirth.

Rule No. 20 (20, 1908)—Stillbirths should not be included in tables of births or in tables of deaths. They should be given in separate tables of stillbirths.

Rule No. 21 (21, 1908)—It is not desirable that midwives be permitted to sign certificates of stillbirths.

Rule No. 22 (22, 1908)—Total births should include children born alive only, and headings of tables should state that stillbirths are excluded.

Rule No. 23 (23, 1908)—Whenever, under foregoing rules, a death should be registered, there should be a corresponding registration at some previous time of a birth; and whenever a stillbirth is registered it should be rigorously excluded from both the statistics of births and deaths.

The sub-committee at present reporting endorses each of the above rules of statistical practice as adopted by the Section on Vital Statistics in 1908.

While it is rare for a product of pregnancy of less than 28 weeks gestation to present evidence of life after complete birth (*i.e.*, action of heart, breathing, movement of voluntary muscle), such instances seem to be of undoubted authenticity and when this does occur it is worthy of special medical record and supporting comment. Under Rule 19, 1908, as amended in 1913, such products are, of course, registered as live births. The committee recommends that the information with regard to period of gestation be noted on the live birth certificate and the supporting comment be made a matter of special confidential record for medical purposes.

Unless gestation has advanced to the 5th month, *i.e.*, after 120 days, the product of pregnancy need not be reported as a stillbirth.

The term *abortion* should be reserved for the expulsion or extraction of the product of conception previous to its presumed viability, usually understood to apply to a fetus of less than 28 weeks from the assumed date of conception (6½ calendar, or 7 lunar months, at which time, in the races prevailing in the United States, the fetus will weigh 1,500 grams or 3¼ pounds and have a length of 35 centimeters or 14 inches).

The term *early abortion* should be applied only to expulsion or extraction of the product of conception prior to the end of the first 12 weeks of pregnancy.

The term *late abortion* should be applied to expulsion or extraction of the product of conception from the end of the twelfth week, or after development of the placenta and up to the 28th week of pregnancy.

The term *premature labor* should apply to the delivery of a fetus capable of surviving, and as usually understood, but not absolutely limited in fact, to apply to the product of conception after 28 weeks or 6½ calendar months or seven lunar months, which in American experience will usually have a weight of 1,500 grams or 3¼ pounds and a length of 35 centimeters or 14 inches.

B.

While the value to science and to society of an exact knowledge of all pregnancies, their duration prior to interruption, at any time prior to term can be logically maintained, nevertheless we believe practical considerations and the weight of administrative procedures and professional traditions are of such strength as to justify us in planning for and promoting registration

of only such stillbirths as are estimated to represent products of conception of 20 weeks' duration or more. This is the period recommended in the model birth registration law.

It is recommended that the influence of the American Public Health Association be exerted in all proper ways to bring concerted action of appropriate professional bodies and other organizations, so that state legislatures may be persuaded to enact new laws or amend existing statutes to require the registration of stillbirths, uniformly defined and by the use of a form approved by the Bureau of the Census for this purpose, and by the use of an approved list of terms describing the cause of the stillbirth comparable as far as practicable with the *International List of Causes of Death,* and that to this end the following organizations be approached for coöperative action in the matter—

U. S. Bureau of the Census
U. S. Public Health Service
Children's Bureau
State and Territorial Health Officers
Conference of State and Provincial Health Authorities of North America
American Medical Association (Sections on Obstetrics, Gynecology, Pediatrics, Preventive and Industrial Medicine, and Public Health)
American Academy of Pediatrics
Association of American Obstetricians and Gynecologists
Association of State Registrars
National Conference on Commissioners on Uniform State Laws
Life Insurance Companies

C. and D.

The text of the face of a suggested standard stillbirth certificate (C), with a list of approved causes of stillbirth printed on the back or reverse (D), is recommended.

E.

Your committee is eager for suggestions regarding this proposed certificate from all the members of the American Public Health Association who are interested in the registration of stillbirths. We believe, in many instances, two or more causes will be simultaneously reported on these certificates and that a manual of joint causes for stillbirths will be needed. No recommendations of a more exact nature are offered on this subject at present except that the experience of selected lying-in hospitals and a few cities be studied systematically to determine the general usefulness of the certificate, the types of causes which are reported, the extent of joint cause reporting, and the most practical means of encouraging uniformity in the practice of registration officials. Following the special studies mentioned above it will be feasible to prepare detailed instructions for certifying causes of stillbirth, and a list of undesirable terms. For the present the committee recommends that the instructions be limited to those shown on the back of the present form as follows:

Describe fully the conditions in the fetus and mother which were associated with the fetal death, *i.e.,* conditions found in the fetus at the time of birth and diseases and conditions of the mother during pregnancy and labor. Indicate the condition you consider the primary cause of the fetal death. For example: the dead fetus was hydrocephalic; the mother had had a mild case of toxemia during pregnancy; the fetus would probably have been live born except for hydrocephalus. Enter under item 34: (a) Fetal—Hydrocephalus—primary. (b) Maternal—Toxemia.

Confidential Inquiry Into Cause of Death

TWO years ago, a report was presented at a meeting of this Section on an experiment made in the Westchester County Health District to determine, first, the inaccuracy present under the existing system of death registration in the statement of two causes of death (namely, syphilis and alcoholism), and second, the reaction of the general medical profession to the use of a confidential form of death certificate. This experiment consisted of interviewing personally a group of 350 physicians, each of whom reviewed all of the death certificates he had signed during a period of 2 years and stated confidentially in which cases alcoholism or syphilis had been a leading or contributory cause of death. The investigator, a physician from the health department, also discussed with each doctor in the group the whole question of whether or not a confidential form of death certificate would result in greater accuracy than can be attained under the existing system. The results may be summarized as follows:

1. Additional data secured confidentially by personal visit for 5,299 deaths resulted in a death rate from syphilis approximately double the original recorded mortality from this cause and a corrected figure for alcoholism 57 per cent higher than the recorded rate. Syphilis was stated on the original certificate in approximately 49 per cent of the cases in which it should have been so certified, and alcoholism in 33 per cent.

2. Practically all of the 365 physicians reporting deaths in the Westchester County Health District during a 2 year period felt that confidential reporting would result in far greater accuracy in the statement of causes of death than does the present official system.

In view of these results and the apparent enthusiasm of the group of physicians concerned, it was decided to follow this experiment immediately with another. This second had as its major object to set up, if possible, a system of voluntary confidential reporting of causes of death. To this end a form was designed which allowed space for a confidential statement of the primary and contributory causes of death. A detachable part of the form which was finally accepted by the County Medical Society contained identifying information, specifically the date and place of death and the cause of death stated on the original certificate. In no place was the name of either the patient or the physician included. Although date and place of death was sufficient information to locate the official death certificate on record in the county office for comparison, the fact that the County Medical Society earlier rejected a form containing on the detachable section the name of the decedent in addition to the place and date of death would make it appear that physicians believed that they were not identifying their patients. Every effort was made to make it clear that the confidential statement could and would be checked with death certificates but that once this was done the identifying data would be detached from the rest of the blank and destroyed.

A number of blank forms and stamped return envelopes were supplied to every physician in the district with the request that one be made out and mailed to the County Commissioner

CONFIDENTIAL STATEMENT

Place of Death ....

Date of Death ....

Certified Cause of Death ....

....

Mail to the Westchester County Commissioner of Health, 148 Martine Avenue, White Plains, as soon as possible after the standard certificate of death is filed with the Registrar.

of Health for every death certificate signed, regardless of whether or not there was any additional confidential information to be given. The project thus roughly described was endorsed by the County Medical Society both through letters to each individual physician and through a notice published in the society's monthly bulletin.

The results were frankly a failure. For the first 2 months after the forms were sent out approximately one-third of the recorded deaths were also reported on confidential blanks. After that only a group of a dozen physicians continued to make reports, and the number of their deaths was negligible. Obviously to fill out and mail routinely a voluntary report of this sort, whose only use is statistical and theoretical, is more than can be expected of busy practising physicians, however interested they may be in possible results.

A total of 210 confidential blanks was returned before it became evident that the project in that form should be abandoned. Although this number is extremely small and could not possibly give results from which any general conclusions may be drawn, they have been analyzed with a view to shedding some light on the very significant question as to how much error, which can be discovered through a confidential inquiry of some sort, there is at present in recording causes of death. This small group of reports is probably fairly representative as far as it goes, inasmuch as it comprises reports on all of the deaths attended by a few physicians over a period of 2 or more months. To be sure, the physicians who reported were those who were especially interested in the project, but comparison with the original survey shows that they were not physicians who had under-reported syphilis and alcoholism any more than others. In a number of cases none of the deaths in a physician's practice were recorded with an incomplete cause on the official death certificate.

Analysis of the 210 confidential blanks reveals the following facts:

1. Information not included on the death certificate was stated on 62 or approximately 30 per cent of the returned confidential reports. In 14, or 6.7 per cent of the total number, this additional information would, if stated on the death certificate in addition to the information already there, result in a change of *International List* classification according to the *Manual of Joint Causes of Death*. Within this group of 210 deaths the following changes in assignment of cause of death resulted:

Syphilis deaths increased in number from 3 recorded deaths to 6. (This result, although based on small figures, checked closely with the results of the original survey.)

Cancer deaths increased from 25 to 28 (12 per cent).

Cerebral hemorrhage declined from 17 deaths to 14.

Deaths from diseases of the heart declined from 66 to 62.

2. Results which are of general interest but resulted in no change in classification were as follows:

Alcoholism was omitted as a contributory cause from the original death certificate in 7 cases. On no original certificate was it given as either a primary or contributory cause.

Syphilis was omitted from a total of 5 certificates. In 2 of these cancer and automobile accident were the primary causes and no change in classification resulted.

Drug addiction was included as confidential information in 2 cases.

CONCLUSIONS

The committee has set itself the problem of determining two facts, the first of which is the relative value of various methods of confidential inquiry into the cause of death. The projects in the Westchester County Health District have shown that through a direct personal contact with the physician information may be obtained successfully, but that a voluntary supplemental report, entirely separate from the death certificate and mailed to a different official agency, is not successful. The first is the most expensive and troublesome method of getting information, and the second the cheapest and easiest. It is hoped that within the coming year a modification and combination of the two methods may be attempted. For example, it might be feasible to mail to each physician at intervals of 3 months a list of the death certificates which he has signed during the period with a request that he state confidentially in each case the primary and contributory cause of death and return the list to the County Department of Health with the names detached. Some system of numbering such lists would have to be evolved inasmuch as it is essential in tabulating the statistical results to know exactly what group of original deaths has been included.

Once a suitable and reliable method of getting the information has been found the second problem is solved—namely, to determine what effect confidential and more complete information has on recorded death rates. At present the only fact that has been discovered is that in the Westchester County Health District the true death rate from syphilis is at least double the recorded rate. It remains to be proved what correction factor should be applied to this death rate in other communities or to the rates from other causes in Westchester and in other areas.

COUNCIL OF THE VITAL STATISTICS SECTION

Forms and Methods of Statistical Practice*

THE report of the committee covered three subjects. The first discussed classification of sub-types of disease and included the following recommendation:

> That whenever a case or death is reported as due to smallpox, an effort be made to obtain from the diagnostician or epidemiologist a statement whether the disease was of the classical malignant type or of the benign type, and to indicate malignant cases or deaths in tables through an asterisk or other symbol leading to an explanatory footnote.

The second part of the report dwelt upon the desirability of promoting the use of selected age groups for expressing death and morbidity rates from certain diseases, *e.g.*, the earlier years of life for the communicable diseases of childhood. It was reported that work along these lines had been begun and that more specific recommendations would be presented at the next annual meeting. The use of standardized rates will also be considered.

The third part of the report consisted of provisionally recommended tables for monthly reports of State Health Departments. The subjects included natality, morbidity, and mortality. This report was presented by Dr. John Collinson as Chairman of the sub-committee on Standard Tables. Suggested table forms were given out at the meeting and discussed. A definitive report will be presented at the next annual meeting.

* Abstract of Progress Report.

Residence Correction

THE Committee on Residence Correction (originally designated as the Committee on the Proper Allocation of Records) was appointed in October, 1926, at the Buffalo meeting of the American Public Health Association. In the course of the following nine years the need of allocating records of births and deaths according to residence (with certain exceptions in regard to deaths from tuberculosis, other chronic diseases, and external causes) has become generally recognized and has been adopted as a routine procedure by many states.

In 1934 the U. S. Bureau of the Census decided that beginning with 1935 its annual reports should be based on the resident and not, as hitherto, recorded numbers of births and deaths. The aim of the committee, namely, to bring about the establishment of a nation-wide system of residence correction having been accomplished, the committee asks that it be dissolved.

Entrance Requirements for Graduate Degrees

University of California

Dr.P.H.—Graduate of an approved medical school.

Ph.D. in Hygiene—Candidates must have completed courses equivalent to those constituting the undergraduate curriculum in public health.

Columbia University

M.S. in P.H.—Graduate of a class A medical school with a degree of Doctor of Medicine or a graduate in arts or sciences having an acceptable degree of Bachelor of Science or Bachelor of Arts, and presenting evidence of having satisfactorily completed college courses in chemistry, physics, bacteriology or general biology, and mathematics. In addition such candidates should have completed a course in medical bacteriology similar to that given in the first year of the School of Medicine.

M.S. in P.H. majoring in Sanitary Science—Graduate of an approved engineering school, having a degree of B.S. in civil engineering, or its equivalent.

Harvard School of Public Health

C.P.H.—Evidence of having had satisfactory training in modern languages, inorganic, organic and biochemistry, biology, physiology, anatomy, histology, pathology and bacteriology. As a rule these requirements will be met by students possessing a bachelor's degree plus the first 2 years in an approved medical school.

M.P.H.—Satisfactory evidence of having received the M.D. degree, or its equivalent, from an approved medical school.

Dr.P.H.—Satisfactory evidence of having received the M.D. degree, or its equivalent, from an approved medical school. To qualify as a candidate, the student is required to pass an examination of the same type as that required to obtain the degree of M.P.H. It is intended to provide the assurance that all men receiving the Dr.P.H. are grounded in the four fundamental subjects and in the field most closely allied to their special interests.

Ph.D. in Hygiene—Properly qualified students in public health, who have no medical degree but who wish to secure a higher degree, may obtain a Doctor of Philosophy in Hygiene. This degree is granted by the university to men, or through Radcliffe College to women.

Johns Hopkins School of Hygiene and Public Health

C.P.H.—Graduate of approved medical school or graduate in arts or science, with adequate courses in physics, chemistry, and biology, and in the basic medical sciences, anatomy, histology, physiology and pathology.

Dr.P.H.—Applicant must be recommended by the head of the department in which he proposes to do his major work as an acceptable candidate. Students not personally known will be accepted only provisionally, final acceptance being conditioned upon the character of the work done.

In addition applicant must be:

a. Graduate of an approved medical school, who has had a liberal education as evidenced by a degree in the arts or the sciences or its equivalent, and who has completed the course leading to a C.P.H. or its equivalent.

b. Student who has fulfilled the requirements as to a liberal education and who has satisfactorily completed 3 years of this course in an approved medical school may be admitted to advanced standing which will permit him to complete the requirements for the degree in 1 year after graduation in medicine, provided arrangements are made to include in the medical course a sufficient number of courses which may be credited toward a C.P.H.; provided, also, that he is prepared, on admission, to enter upon advanced work in a selected major subject. During the year of residence, such a student, in addition to work in the major subjects, will be expected to take such of the courses leading to a C.P.H. as have not been absolved.

Sc.M. in Hygiene—*A degree in arts or science, or in medicine, from an approved school.

Certificates of the completion of adequate courses in physics, chemistry and biology.

Sc.D. in Hygiene—

a. *A degree in arts or science, or in medicine, with a reading knowledge of French and German.

b. Certificates of the satisfactory completion of adequate courses in physics, chemistry, and biology.

c. Certificates of the satisfactory completion of adequate courses in anatomy including histology, physiology, and pathology.

d. In exceptional cases, on the recommendation of the head of a department, a candidate may be accepted who offers in place of (c) satisfactory evidence of special training of an advanced character in subjects fundamental to his main field of work.

e. Not less than 1 year before being presented for the degree, the candidate will be required to pass an oral examination before a committee of the faculty. Final acceptance as a candidate for the degree will be conditioned upon favorable recommendation by the committee.

Massachusetts Institute of Technology

C.P.H.—Graduate in arts or science from a recognized institution or a medical degree from a class A medical school or have had professional training equivalent thereto.

Dr.P.H.—Graduate in arts or science from an institution of recognized standing or who have received the M.D. degree from a Class A medical school with at least 2 years of college training before entering the medical school.

University of Michigan

M.S. in P.H., D.P.H.—Candidates for graduate degree in public health, for the master's degree, M.S. in P.H., as well as for the doctorate, D.P.H., are obviously better equipped for their work if they already hold the degree of Doctor of Medicine from an accredited school. Holders of a baccalaureate degree from an accredited college, however, may be admitted to study for the master's degree or even, in exceptional cases, for the doctor's degree.

University of Toronto

D.P.H.—Graduate in medicine of this university or some other university recognized for this purpose by the Senate.

University of Western Ontario

D.P.H.—Graduate of approved School of Medicine.

Wayne University College of Medicine

Dr.P.H.—Graduate of Class A medical college. Applicants who have received the Degree of Doctor of Medicine since 1921 will be required to present, in addition to the diploma from the medical school, evidence of 2 years of academic instruction obtained in an approved school of arts and sciences.

Yale University

M.P.H.—Graduate in arts or sciences from a college or technical school of high standing or 2 years' study in a medical school of high standing.

Dr.P.H.—Graduate in medicine from a medical school of high standing.

* In exceptional circumstances, students without a college degree may, by special action of the Advisory Board, be accepted as candidates for the degree Sc.M. or Sc.D., provided they furnish satisfactory evidence of preparation fully equivalent to that usually represented by an academic degree, and of unusual accomplishment.

Foundations Appropriating Funds for Medicine and Public Health in 1934*

THE following Foundations made grants in excess of $5,000 for Medicine and Public Health:

American Foundation for Mental Hygiene	$ 10,033

40% less bulk—
clear in color

ANTITOXINS

GLOBULIN *Lederle* MODIFIED

In each pair of syringes shown in the illustration below, the left-hand one is the antitoxin as sold before October 19, 1935. The companion is the style now sold—20 to 40% volume reduction, lower viscosity, the major percentage of troublesome proteins discarded and the remainder modified.

Radical reduction of serum sickness follows as demonstrated by months of experience, with, for instance, the 1500-unit dosage of Tetanus Antitoxin in four surgical clinics.

Now being supplied — *Lederle's* Globulin Modified Antitoxins for Diphtheria, Erysipelas, Gas Gangrene, Scarlet Fever, Tetanus and Tetanus Gas Gangrene, all Council-Accepted.

A BRIEF REVIEW OF THE RESEARCH ON BRAN

WHAT are the scientific facts on bran? To answer this question, the Kellogg Company has aided, for some years, research in leading university laboratories. The results, combined with other independent scientific tests, give you an accurate picture of this product:

Research has established the effectiveness of bran in correcting constipation due to insufficient "bulk." (1)

Other studies indicate that bran is a wholesome food for normal people, and that the laxative effect of bran is not reduced by continued use. (2)

Laboratory measurements (3) have proved that bran is a good source of vitamin B, and (4) that it is rich in iron.

Further tests have demonstrated that, with some individuals, the "bulk" in fruits and vegetables is largely broken down in the alimentary tract. So bran is often the more effective source of "bulk." (5)

Kellogg's ALL-BRAN is accepted by the American Medical Association Committee on Foods. It is usually more satisfactory for correcting atonic constipation than the continued use of medicines. A few individuals have diseased or highly sensitive intestines. In these special cases, any form of "bulk" is, of course, inadvisable.

Kellogg's ALL-BRAN may be served as a cereal, or made up into muffins, waffles, breads, etc. It is much more effective than part-bran products. Eat ALL-BRAN regularly for regularity. Sold by all grocers. Made by Kellogg in Battle Creek.

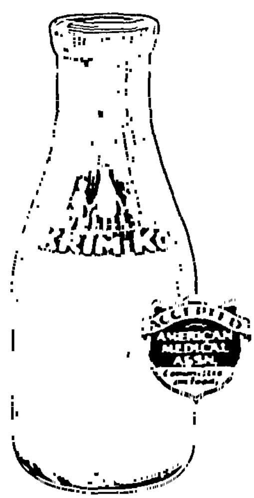
INDEX TO ADVERTISERS

"But, Doctor, I Can't Drink Milk!"

How many times have physicians and dentists heard that answer—when they suggest "a quart of milk a day". Surveys show a surprisingly large percentage of children and adults who don't drink milk because of taste prejudices. For such cases—why not recommend Krim-Ko, a delicious chocolate flavored drink made from pasteurized milk from which part of the fat has been removed and to which chocolate, cocoa, sugar and small amounts of flavorings have been added. Krim-Ko contains *all* the calcium and other valuable food elements—such as phosphorus, vitamin G--found below the cream line in milk. Krim-Ko is equal in food energy value to standard market milk. If you will get in touch with the dairy handling Krim-Ko in your town, we have arranged to furnish you with samples of fresh pasteurized Krim-Ko for yourself and selected patients—without cost or obligation.



Krim-Ko is chocolate flavored, sweetened partially defatted milk (added tapioca-salt)

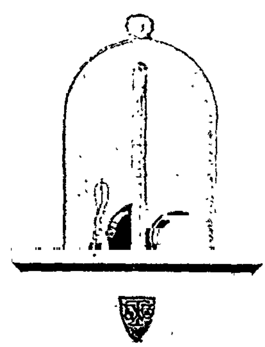
THE CHLORINATION DOLLAR

MUST BUY...DEPENDABILITY



NOT only for today but for tomorrow—for years of tomorrows—dependability is essential to chlorination. Protection of Public Health by the chlorination of water or sewage allows no halfway measures, no slipshod operation, no failure due to inadequate equipment.

With W&T Visible Vacuum Chlorinators, dependability is assured—together with accuracy, ease of control and reduced maintenance costs. An acknowledged leader for today, the W&T Visible Vacuum is also the Chlorinator of tomorrow—designed and built for years of accurate, unfailing, trouble-free service.

Tomorrow's taxpayers will thank you for today's choice of W&T Visible Vacuum Chlorinators.

Poliomyelitis in North Carolina in 1935*

CARL V. REYNOLDS, M.D., AND J. C. KNOX, M.D.
State Health Officer; and Director, Division of Epidemiology, State Board of Health, Raleigh, N. C.

NORTH Carolina has had much publicity this year because of its poliomyelitis epidemic. Inasmuch as this epidemic was one of the few ever described in a latitude so far south, it was not only of newspaper interest but also of scientific interest.

North Carolina is about 650 miles in length from its coastal boundary to its western mountainous boundary. The epidemic of poliomyelitis was confined largely to the east central section about 200 miles from the coast and 300 from the mountains. Considering the length of the state, our coastal and mountainous sections were as far removed from the center of the epidemic as though it had occurred at some distant point, *e.g.*, Washington, D. C., or possibly Savannah, Ga.

In studying our outbreak of poliomyelitis it may be interesting to observe that North Carolina lies in about the same latitude as southern California, approximately 36° north. The longitude is between 75° and 90° west. We have, from May through October, a mean temperature of 60.06°, and a mean rainfall of 27.57 inches. From November through April we have a mean temperature of 47.45° and a mean rainfall of 21.90 in. Eastern North Carolina has a mean temperature of 62.1° and a mean rainfall of 4 in.; central North Carolina a mean temperature of 60.2° and a mean rainfall of 3.99 in.; western North Carolina a mean temperature of 54.5° and a mean rainfall of 4.46 in. The only other recorded epidemic of poliomyelitis in this latitude comparable in extent to that in North Carolina this summer occurred in Southern California in 1934.

The average number of cases of poliomyelitis for the past 5 years has been approximately 73 cases per year. Our peak year, prior to 1935, was 1929 in which we had 133 cases reported. From January through October, 1935, 641 cases had been reported to the State Board of Health, with 59 deaths. The attack rate per 100,000 for the epidemic was 19.62; the death rate approximately 9 per cent.

In the preëpidemic period, January

* Read at the Fourth Annual Meeting of the Southern Branch, American Public Health Association, in St. Louis, Mo., November 19, 1935.

through May 15 this year, 39 cases and 11 deaths were reported. The epidemic appeared in the last half of May, with 59 cases reported for 2 weeks; 232 cases were recorded as having their onset in June; 204 in July; 56 in August; and 36 in September. The peak of the epidemic, by onset, occurred in June. Reviewing the records of poliomyelitis in North Carolina for the past 10 years, we find that the highest incidence occurred in August, with an average of about 18 cases.

Analysis of cases for 1935 reported as having onset January–September (622 cases) shows 8 per cent were under 1 year of age, 43 per cent were 1 to 4 years, 27 per cent 5 to 9, 9 per cent 10 to 14, 5 per cent 15 to 19, 2 per cent 20 to 24, 2 per cent 25 to 34, and 3 per cent 35 years and over (unknown age: under 1 per cent). The age distribution is noticeably greater in the 5–9 year group than in the past 5 years.

Of 622 cases, 338, or 54 per cent, were males; 284, or 46 per cent, females; 480, or 77 per cent, were white; 124, or 20 per cent, Negroes; 14, or 2 per cent, Indians; 4 race unknown.

Sixty-five per cent were rural and 35 per cent urban. The term "rural" applies to towns of less than 2,500. The attack rate per 100,000 among whites was 21.48; among Negroes, 13.50; among Indians 84. The population of North Carolina is 70 per cent white, 29½ per cent Negroes, ½ of 1 per cent Indian.

Among the 641 cases reported January–October there were 12 in which 2 occurred in the same family. Three had onset the same day as the original case; 2, 1 day later; 3, 2 days later; 1, 4 days later; 1, 6 days later; 1, 8 days later; and 1, 13 days later.

From the 181 case investigations the following information was obtained: 142 had spinal type of paralysis with 1 death; 14 had bulbar type of paralysis with 9 deaths; 6 had mixed types (bulbar-spinal) paralysis with 2 deaths; and 19 were non-paralytic.

Of the 100 counties, 80 reported poliomyelitis. Johnston, in the east central section, had the highest attack rate: 85.03 per 100,000; 52 had an attack rate of 10 or higher per 100,000. The mean average attack rate for the entire state for 14 years has been 1.9 per 100,000. Wake County (in which Raleigh is situated), adjoining Johnston, reported the highest number of cases, 55. Durham County, adjoining, 51 cases; Johnston, 49 cases. If there was any radial spread from Raleigh (which we may consider as having been the center of our epidemic), it was in a northerly and northwesterly direction. The counties just north of Wake border on Virginia.

The control policies adopted by the North Carolina State Board of Health during this epidemic are summarized as follows:

1. Immediately upon the appearance of an abnormal incidence of this disease, county and city health officers in North Carolina were informed by letter of the control policies of the State Board of Health.

2. Attendance at public gatherings, irrespective of nature, was strongly discouraged, especially for children.

3. Summer camps were advised not to admit patrons from affected areas.

4. Summer camps were advised not to permit unrestricted visiting by their patrons.

5. The Board of Health, by press, radio, and correspondence, warned against treatment by "quacks" and the use of untried medical "cures."

6. The Board of Health advocated the use of prophylactic vaccines *only* in controlled studies.

7. The Board furnished to each physician reporting one or more cases of poliomyelitis a copy of "Practical Suggestions on Poliomyelitis," a digest prepared by a Special Committee on Poliomyelitis for use in connection with the Poliomyelitis Scientific Exhibit at the Milwaukee Session, 1933, of the American Medical Association. It was hoped that this pamphlet would be helpful

to those physicians who were seeing poliomyelitis in their practice for the first time or after an interval of many years. It was felt that this was a service that the board could distinctly render, and the comment received from various physicians of the state was favorable.

8. The board also furnished to physicians, for each case reported, a questionnaire form to be filled in and returned. To date 181 of these have been returned and are analyzed elsewhere in this paper.

9. The board rendered consultant diagnostic service to any physician requesting it.

10. The board advised that all suspicious cases of poliomyelitis be treated as poliomyelitis until definite diagnosis was made.

Since the State Board of Health is state-supported, it was felt that any information on this epidemic collected by the board was public property and, therefore, factual information was made available at all times.

The poliomyelitis vaccines manufactured by Kolmer and Brodie were used in North Carolina during the epidemic. The Brodie vaccine was used in control studies; the Kolmer vaccine was used by private physicians.

CONCLUSIONS

During the epidemic observation led the board to conclude that:

1. A daily bulletin, in which facts are given, inspires confidence, secures coöperation, and dispels fear.

2. Early diagnosis and specialized care are the best means of preventing permanent paralysis.

3. The best means of prevention is in avoiding contacts.

4. So far, nothing has been learned from the vaccination of the 300 children in the City of Greensboro, with the Park-Brodie poliomyelitis vaccine. No cases of poliomyelitis have developed in either the control or the vaccinated groups.

5. This is also true of the Kolmer poliomyelitis vaccine, no complete records being available. Of this vaccine 3,327 c.c. was distributed by Dr. Kolmer to North Carolina physicians; the number of persons inoculated is not known.

6. In the experiment with the Park-Brodie vaccine, local abscesses occurred in 6 per cent of cases; 12 per cent developed nodules at the site of intradermal inoculation; 12 per cent developed medium size indurations.

7. A check of the field experiment, by laboratory immunity tests on both the vaccinated and the unvaccinated children, would be of considerable value in determining the efficacy of the vaccine. This check is already being made.

8. One in 4,600 developed the disease. Assuming that the vaccine is 100 per cent effective, is it a wise public health procedure to use it when the attack rate is so low?

9. Assuming that the vaccine is effective, would not the reactions, abscesses, nodules, indurations prevent its general use?

10. Assuming that the vaccine is effective, would not the incidence of the disease decry its general use?

11. Assuming, again, that the vaccine is effective, would not the potential danger of its producing paralysis decry its use?

12. If public health officials were to advocate a vaccine whose value had not been demonstrated, it would reflect itself in the loss of public confidence in those vaccines whose value is definitely known.

We must know the past to appreciate the present and prepare for the future.

Poliomyelitis in Virginia During 1935*

I. C. RIGGIN, M.D., F.A.P.H.A.
State Health Commissioner, Richmond, Va.

PREVIOUS to this year there have been 2 periods in which there was an unusual prevalence of poliomyelitis in Virginia—in 1916 and 1917 when the cases were distributed throughout the state, and in 1929, when cases occurred particularly in the southwest section. There are on record 345 cases in 1916; 318 in 1917; and 325 in 1929.

Records of the State Department of Health show that poliomyelitis was first reported in Virginia in July, 1910, and in that year there were 679 cases, a number greater than in any succeeding year until the present. Up to November 1, 1935, 674 cases and 37 deaths from poliomyelitis have been reported to the State Department of Health. The June cases showed the usual symptoms of poliomyelitis including paralysis or definite muscular weakness, and the expected age distribution of between 70 and 80 per cent of the cases under 10 years of age. Most of these cases were reported from the southern counties bordering on North Carolina where the disease appeared to be unusually prevalent. From the southern counties the disease spread, apparently along the routes of travel, into several sections of the state, though it reached epidemic proportions in only a few counties. As can be seen in Figure I, a peak was reached in the week ending July 20. After a slight recession lasting about 1 week, a wave of cases showing no paralysis or muscular weakness, classified as non-paralytic, first appeared in Richmond. Later, cases developed in Albemarle County, Roanoke County, and other sections.

Coincident with the change in the type of cases reported is the change in age distribution. Up to August 1, 67.7 per cent of the patients were under 10 years of age; by August 14 the percentage under 10 had dropped to 62.2 and by September 1 to 59.7 per cent.

This change in the clinical type of cases reported and their age distribution is brought out more clearly in Figure II. To date, 525, or approximately 80 per cent of the questionnaires sent to physicians reporting cases of poliomyelitis, have been received and analyzed. The cases have been divided into 2 groups: those showing paralysis or any muscular weakness, however slight or transitory (271), and those having no paralysis or weakness (254). The solid line shows the paralyzed and the dotted line the non-paralyzed group, plotted by date of onset.

The cases in the paralyzed group are best described as typical poliomyelitis, having the usual symptoms including more or less extensive paralysis or muscular weakness—67.5 per cent of the cases in this group were under 10

* Read at the Fourth Annual Meeting of the Southern Branch, American Public Health Association, in St. Louis, Mo., November 19. 1935.

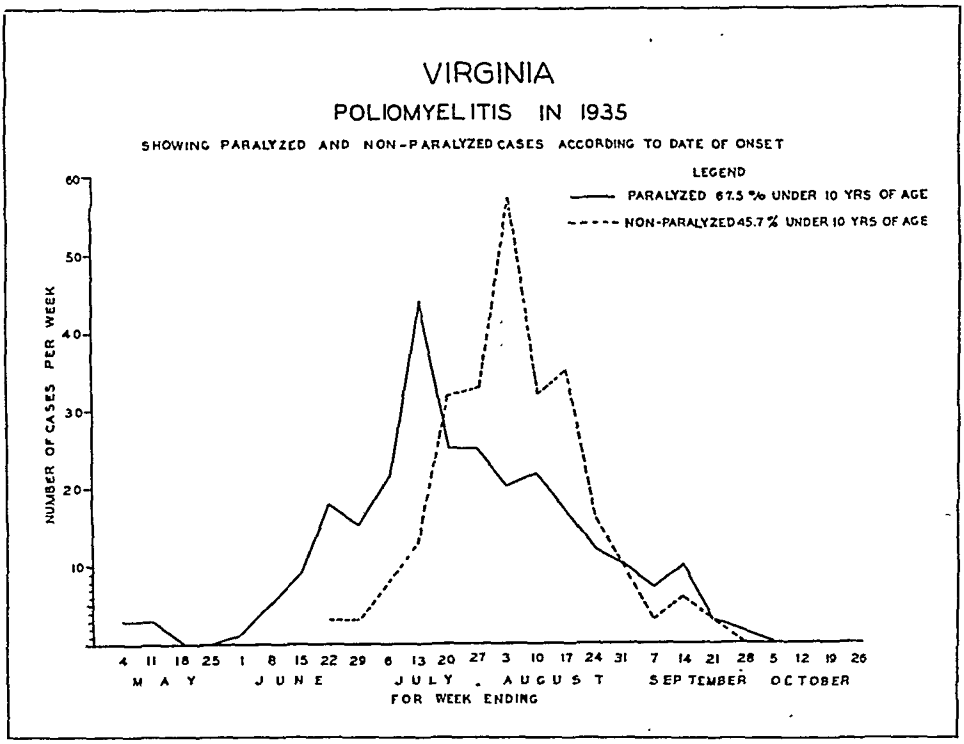

FIGURE I

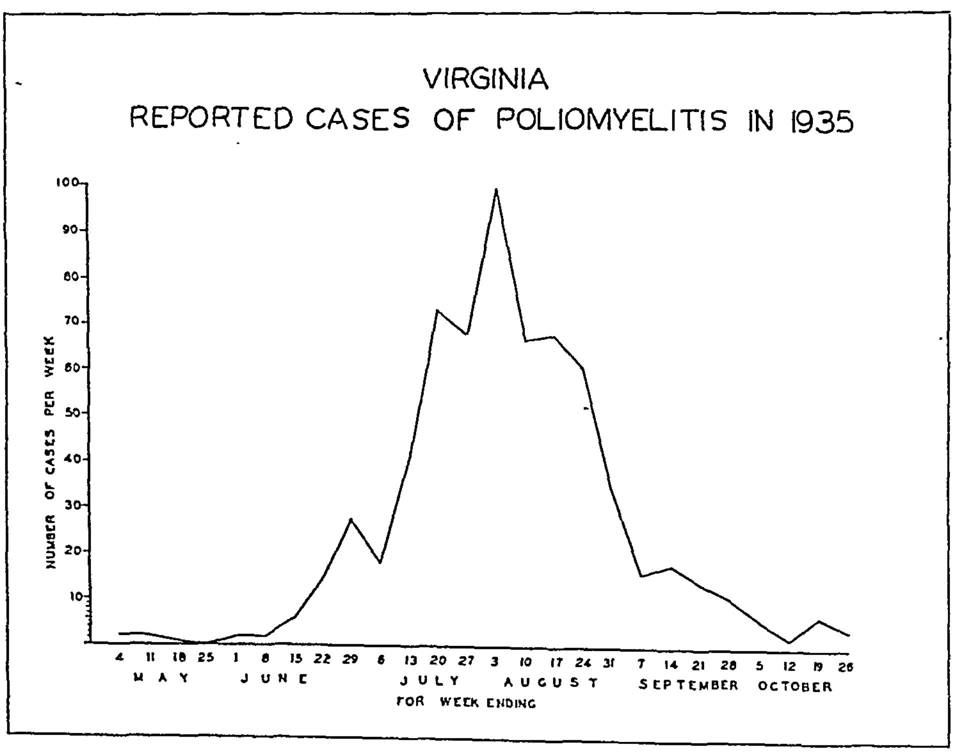

FIGURE II

years of age. The peak of the cases with paralysis was reached July 13, since which time the decline has been almost steady.

The cases showing no paralysis or muscular weakness are characterized by nausea and vomiting, a slightly stiff neck or back, and headache so severe in many cases that morphine was used. These symptoms lasted only 2 or 3 days in the majority of cases, and there was no paralysis or weakness. Moreover, a much higher percentage of the cases were in older people, for only 45.7 per cent of the non-paralytic cases were in children under 10. The first non-paralytic case did not occur until June 22 and the peak was not reached until the week of August 3, 2 weeks after the peak of the paralytic cases. When these two curves are added together, the double peaked curve shown in Figure I is produced and the increasing age of the reported cases is explained.

To summarize, in 1935 up to November 1, 674 cases of poliomyelitis, including 37 deaths, were reported to the State Department of Health. The disease reached almost every section of the state though it was unusually prevalent in only a few counties. It is remarkable how readily these cases, occurring mostly in a little over 2 months, separate into two distinct groups having marked differences. The paralytic cases, appearing first in the counties bordering on North Carolina and spreading along the routes of travel throughout the state, had symptoms typical of poliomyelitis, and the usual age distribution. A second wave, of non-paralytic cases, characterized by short duration of symptoms, and no paralysis, reached its peak 2 weeks later. A great many of these cases occurred in older people. The significance of these facts is as yet undetermined.

Federal Funds for Maternal and Child Welfare

IN each state the responsible official through whom the federal funds for general health work and maternal and child health work will be administered is the state health officer. He is faced with a great responsibility and will undoubtedly need the coöperation of all thinking citizens within his jurisdiction. It is obvious that, if the maximum sums authorized are appropriated and if matching appropriations are provided by state legislatures, state health departments will suddenly be possessed of larger sums than they have ever previously had to administer. Sudden expansion is always fraught with great danger. There is no time to experiment on a small scale, to test, to weigh, to modify, to adapt or perhaps to reject plans. Among the gravest problems will be that of qualified personnel. There is a great dearth of adequately trained health administrators, sanitarians, engineers, technicians, and public health nurses. The training provisions which will be found in the act will take time to put into effect.—W. W. Bauer, *A.M.A. Bull.*, Dec., 1935.

Anterior Poliomyelitis in Kentucky During 1935*

A. T. McCORMACK, M.D., F.A.P.H.A., (*Life Member*)
AND FRED W. CAUDILL, M.D.
State Health Commissioner; and State Epidemiologist, Louisville, Ky.

POLIOMYELITIS in Kentucky has shown a fairly definite periodicity between 1911 and 1935, the increases in incidence recurring at approximately 7 to 8 year intervals. The expectancy during interepidemic years averages from 20 to 40 cases annually. The last epidemic year previous to 1935 was 1927, when 192 cases were reported.

The 1935 epidemic really began in 1934, when 118 cases of poliomyelitis were reported. This was a very marked rise in prevalence compared with the years between 1927 and 1934, during which the annual average was 37 cases. Approximately 90 per cent of the cases reported in 1934 occurred during the summer and early fall. The disease abated during November and December, 1934, and only 8 cases were reported in the state from January 1 to July 1, 1935. During July the incidence showed a sudden and marked rise, 43 cases being reported. Of these, 23 occurred in 2 adjacent counties in the southwestern part of the state, Warren County reporting 12 cases and Edmonson County 11 cases. During that month the disease showed a gradual increase in prevalence also in Louisville and Jefferson County, 9 cases being reported from the City of Louisville. Hence, Warren, Edmonson, and Jefferson Counties constituted the 3 chief foci of prevalence of poliomyelitis in Kentucky in July. The remaining 11 cases reported during that month were in widely scattered sections of the state.

During August, 114 cases were reported, 61 of which occurred in Louisville and Jefferson County, the remaining 53 reported cases being fairly uniformly distributed among 12 counties lying southwest of Louisville, in what is known as the Mississippi Plateau, with an occasional case in the eastern and far western parts of the state.

In September, reports of 97 cases came in, 39 of which were in Louisville and Jefferson County. The other 62 cases were distributed among the 12 counties which lie southwest of Louisville.

During October, Louisville and Jefferson County showed a marked decrease in prevalence, but were still reporting more cases than any other single locality in the involved area. The situation in the rest of the infected part of the state was also showing definite and distinct improvement. Cases reported in October aggregated 46, of which 14 were in Louisville and Jefferson County, the remaining 32 distributed throughout the rest of the infected section of the state. The number of cases reported during the first week of November indicates that prev-

* Read at the Fourth Annual Meeting of the Southern Branch, American Public Health Association, in St. Louis, Mo., November 19, 1935.

alence of the disease is now back to what may be considered normal.

SUMMARY

A total of 308 cases of infantile paralysis in Kentucky was reported from January 1 to November 1, 1935. The months of greatest prevalence were July, August, September, and October. The section of the state showing the highest incidence comprises Louisville and Jefferson County and an area southwest of Louisville, known as the Mississippi Plateau and embracing Bullitt, Nelson, Hart, Barren, Edmonson, Grayson, Breckinridge, Warren, Logan, Muhlenberg, Hopkins, and Daviess Counties. This section includes about one-fourth of Kentucky's area.

Reported deaths due to poliomyelitis numbered 25, giving a specific fatality rate of 8.3 per cent. Approximately 67 per cent of those recovering from attacks of the disease showed some degree of paralysis, which ranged from a slight weakness in a single muscle group to a profound paralysis of one or more extremities. Fifty-seven per cent of the cases occurred in males; 43 per cent in females. Ninety-one per cent were in white children; 9 per cent in colored children. Cases and deaths in the various age groups are shown in Table I.

TABLE I

Age Group	*Cases*	*Deaths*
0– 4	137	17
5– 9	86	4
10–14	50	2
15–19	21	2
20 up	14	0
Total	308	25

It will be noted that the age group in which most cases occurred was that under 5 years. Seventeen of the 25 deaths were in children in this group.

New York Poliomyelitis Report Issued

A PRELIMINARY report on the poliomyelitis epidemic of 1935 has been published by the New York City Department of Health. About 1,900 cases had been registered up to the time of this report in October, which compares with 4,100 in 1931 and 9,000 in 1916.

The report points out the shifting of the incidence to the higher ages. In 1907, 86.6 per cent of the cases were in children under 5 years of age. In 1935, 32.8 per cent occurred in this age group. The case fatality also varied in these four epidemics. In 1907 the case fatality rate was estimated at 5 per cent; in 1916 it was 27 per cent, in 1931, 12.18 per cent, and in 1935, 4 per cent.

Of particular interest to administrative health officers will be the fact that, after due consideration, it was decided to open the city schools at the regular time. The department believes that this policy was sound because of the fact that no increase in prevalence followed the opening of the schools.

Poliomyelitis in Tennessee*

W. C. WILLIAMS, M.D., F.A.P.H.A.
State Commissioner of Public Health, Nashville, Tenn.

THE poliomyelitis problem in Tennessee for 1935 hardly justifies a report at this time since the actual number of cases was only slightly in excess of the average incidence experienced through recent years. Fortunately for the public, the greatest prevalence was noted in the newspapers and practically every case occurring was commented on in more than one paper.

The disease reached epidemic proportions in only 2 areas of the state. The greatest problem was found in the 4 counties of East Tennessee located in the extreme northeastern section of the state immediately adjacent to North Carolina and Virginia. The second area was in the northwest portion of Middle Tennessee, adjacent to the Kentucky line.

For the first 10 months of 1935, 78 cases with 15 deaths have been reported. For the corresponding period of 1934, there were 59 cases and 27 deaths. The case fatality rates were 19.2 and 45.4 for the years 1935 and 1934, respectively. While we have no evidence to support the statement, it is quite likely that the majority of cases reported were those showing paralysis; hence, the actual number of cases known is much smaller than it is reasonable to assume occurred. The distribution of cases was more or less normal, and while the number of cases is rather small, it is interesting to note that 62 per cent of those reported were in children under 10 years of age, with 72 per cent residing in rural areas. The case incidence, based on proportionate population, in the white was about twice that in the colored. The epidemic, if we may call it that, reached its highest incidence on or about August 1.

The following control measures were advocated:

1. Encouragement of prompt reporting by physicians and others of all positive or suspected cases with rigid quarantine of all cases and contacts. While the control procedure may or may not have been of any particular aid in controlling the epidemic, nevertheless, for policy's sake, it was deemed advisable to do something.

2. Newspaper articles in the form of general preventive measures released from time to time. An effort was made to give facts and at the same time avoid arousing public hysteria.

3. In two of the eastern areas, which incidentally were quite closely connected with the North Carolina and Virginia areas, being on the main transportation routes, the local boards of health instituted control measures for the younger age group—all children under 15 years of age were required to remain away from school, public gatherings, and downtown areas for a period of 2 weeks. While this may not have had any effect, it is interesting to observe that the disease apparently subsided with the institution of these measures.

4. Diagnostic consultant service available through the State Health Department to all part- and full-time county health officers upon request. There was no state-wide program for rendering assistance in the treatment of reported cases.

5. Immunizing agents in the form of vaccine (Park-Brodie, and Kolmer products) were neither recommended nor used as a routine control measure.

Poliomyelitis in Charlottesville, Virginia, and the Adjacent County of Albemarle*

W. W. WADDELL, JR., M.D., AND C. W. PURCELL, M.D.
Department of Pediatrics, University of Virginia, University, Va.

WITHIN the past few months poliomyelitis has been reported throughout the State of Virginia to an extent never before recorded. Not since the influenza epidemic of 1918 and 1919 has the populace of this state been so acutely concerned with its state of health, and undoubtedly there has been sufficient cause for this very manifest anxiety. It must be admitted that in certain sections of Virginia poliomyelitis has occurred in serious epidemic proportions. Charlottesville and Albemarle County have been publicly referred to as a "hot-bed" of poliomyelitis; and if one cares to base an opinion on figures made public, this would certainly seem to be a proper characterization.

In the clinics at the University of Virginia Hospital we have observed 111 patients who, in our opinion, were suffering from poliomyelitis and were so certified to the proper authorities. In every case the diagnosis was confirmed or strongly suggested by examination of the cerebrospinal fluid. The purpose of this paper is to describe clinically these cases as we have observed them, and to discuss briefly certain very pertinent facts of medical interest and importance. In view of the difference of opinion and conflict of emotions resulting from our recent experience, a discussion of this subject would seem particularly desirable at this time.

When poliomyelitis first appeared in Charlottesville and surrounding sections, it became necessary for the University Hospital to adopt a policy concerning the admission of cases of this disease. Due to physical conditions which made impossible adequate isolation of patients, hospital authorities made it a rule to accept no patient who could be adequately cared for in the home. The majority of the patients described in this report were, therefore, seen in the out-patient clinics. Thirty-eight were observed by those in charge of the adult service, and 73 by those in charge of the pediatric service. Since it was necessary to return these patients to their homes, in many instances only one examination was afforded during the acute stage of the disease. In evaluating this series, particularly as regards the frequency of any one sign or symptom, it must be remembered that the majority represent out-patient cases, most of them seen only once. Nineteen patients were treated in the hospital, and afforded a better opportunity for study. Forty-seven of the patients from the department of pediatrics were subsequently

* Read at the Fourth Annual Meeting of the Southern Branch, American Public Health Association, in St. Louis, Mo., November 19, 1935.

brought back for a follow-up examination after the period of quarantine had expired.

As with previously reported epidemics the disease has been observed chiefly in children and young adults. The youngest case was 8 weeks of age and the oldest was 35 years. Table I shows the incidence in the various age groups.

TABLE I

AGE GROUPS

Youngest 8 weeks		7 to 8 years	6
Under 6 mos.	5	8 to 9 years	7
6 mos. to 1 yr.	3	9 to 10 years	3
1 to 2 years	6	10 to 11 years	5
2 to 3 years	13	11 to 12 years	3
3 to 4 years	3	12 to 15 years	12
4 to 5 years	6	16 to 20 years	9
5 to 6 years	8	21 to 25 years	12
6 to 7 years	5	26 to 30 years	4
31 to 35 years	1		

Under 12 Years	73 Cases
Over 12 Years	38 Cases

The onset has been sudden and characterized in most instances by fever, headache, vomiting, and stiffness of the neck and back, this stiffness being associated with pain in many instances. This group of symptoms has been so constantly present that the history of one might well serve for the majority. This has been especially true as regards the older children and adults.

Fever was present at the time of examination in 60 cases. While the recorded temperature of our patients varied from normal to 105° F., it must be remembered that the degree of temperature naturally varied in relation to the time of onset. The average temperature at the time of examination ranged from 101° F. to 102° F.

Headache was the most common finding, occurring in 83 of the 111 cases. The headache was usually frontal and was made worse when the patient attempted to sit up. The incidence of headache was very striking, even in the younger children, and it must be admitted that headache is not a common childhood complaint.

As in previous epidemics the most pathognomonic of all signs was stiffness of the neck and spine. Efforts to induce flexion of the spine caused marked "splinting" in a fair proportion of our cases, and evidence of stiffness of the neck and back was noted in 37.9 per cent. A typical "poker spine" was observed more frequently in older children and adult patients.

Nausea or vomiting occurred 69 times as an early sign, and diarrhea 10 times. In some instances vomiting was a very troublesome feature, and interfered with symptomatic treatment.

Sore throat was a complaint in 5 instances, and many patients not complaining of soreness showed on inspection marked injection of the tonsils and posterior pharyngeal wall. Coryza was noted in only 2 instances.

Hyperesthesia was noted less frequently perhaps than in previous epidemics. Pain in the extremities was present in 10 patients; 20 complained of abdominal pain; and 1 was sent to the hospital by the attending physician with a diagnosis of acute appendicitis. A not infrequent sign was pain and soreness when the eyes were rotated and occasionally these patients objected to bright light.

Listlessness or actual drowsiness was observed 17 times. Convulsions were noted in 2 patients, the older being 5 years of age and the younger 2 years.

Change in the reflexes was common. Exaggerated reflexes early in the disease was the rule; examination later often showed marked diminution or actual loss of deep reflexes previously hyperactive. We agree with other observers that reflexes in infants and very young children are apt to be uncertain and unreliable. It may be stated with a reasonable degree of accuracy that reflex changes were present in 47.8 per cent of our cases.

TABLE II

SYMPTOMS AND SIGNS

	Cases	Per Cent		Cases	Per Cent
Headache	83	74.7	Pain in extremities	10	9.0
Vomiting	62	55.9	Nausea	7	6.3
Temperature on examination	60	54.0	Sore throat	5	4.5
Change in reflexes	53	47.8	Difficulty in breathing	3	2.7
Pain and stiffness of neck or back	42	37.9	Dizziness	2	1.8
Evidence of muscle weakness	24	21.6	Coryza	2	1.8
Pain in abdomen	20	18.0	Convulsions	2	1.8
Listlessness or drowsiness	17	15.3	Unable to void	2	1.8
Diarrhea	10	9.0	Enlargement of spleen	2	1.8
			Unable to swallow	1	0.9

Respiratory difficulty was observed in 3 patients and in 1 this made necessary the use of the respirator over a long period of time.

Retention of urine was noted in 2 instances, being sufficiently obstinate to require the use of a catheter. In both patients this condition was completely relieved in a few days.

Enlargement of the spleen was a confusing finding in 2 patients, and typhoid fever with meningismus had to be ruled out as a probable diagnosis. The usual laboratory procedures diagnostic of this disease were negative. The subsequent course of the disease substantiated the diagnosis of poliomyelitis.

Table II shows the frequency of the various symptoms and signs observed.

A most interesting feature has been the infrequency of paralysis compared with the number of individuals affected. Twenty-four of our 111 cases showed definite muscle weakness or actual paralysis. It must be remembered that the majority of the patients were seen only once, and that transient muscle weakness may have occurred and probably did occur subsequent to our examinations. It is by no means easy to measure muscle weakness in certain groups of muscles and we admit that our ability to detect this sign improved very noticeably with further acquaintance with the disease. This was particularly true with infants and young children. It seems likely that physicians for many months to come will see patients with weakness in certain muscle groups as well as changes in posture and other evidence of diagnosed and undiagnosed poliomyelitis. We were able to detect muscle weakness in 21.6 per cent of the patients, and a considerable number showed weakness or actual paralysis after being discharged from quarantine.

The various regions of the body showing muscle weakness or actual paralysis are indicated in Table III.

TABLE III

TYPES OF PARALYSIS

Paralysis of one or both legs	10
Paralysis of one or both arms	5
Combined paralysis of legs and arms	5
Isolated paralysis of cranial nerve	2
Combined paralysis of spinal and cranial nerves	3

Total—24 patients or 21.6%

The average duration of acute symptoms was 3 to 5 days. In 25 cases in which this fact could be accurately determined the average was 4.4 days. An illness of 36 to 48 hours was frequent.

SPINAL FLUID

One or more spinal fluid examinations were made in each case. All laboratory tests were done under the

direction of Dr. William E. Bray, Professor of Clinical Diagnosis, at the University of Virginia, and we acknowledge our appreciation of his helpful advice and coöperation.

In every instance the spinal fluid was noted as clear or, at most, slightly opalescent. The pressure appeared normal or perhaps slightly increased in a few instances.

Increase in cells while present in most cases, has been a variable factor. It is generally accepted that the earliest pathological change in the nervous system is hyperemia. It is not surprising that marked differences in the cell count have been observed in this series of cases as in all others reported. The degree of cell increase was in no way proportionate to the severity of symptoms or the occurrence of paralysis. A cell count above 12 has been considered an abnormal finding. In this series we found 39 cases with a cell count less than 12 but in every one there was a noticeable increase in spinal fluid protein. What one finds in the way of cell increase may vary with the time at which lumbar puncture is performed. We found 39 cases in which lumbar puncture, performed within 24 to 36 hours of the acute illness, showed only increase in the protein content of the spinal fluid. Punctures performed several days later on 8 of these patients showed the characteristic cell increase in 3. Our observation of the cell count has ranged as follows: 39 cases with a count below 12; 26 between 20 and 60; 13 between 60 and 100; 12 between 100 and 200; 15 above 200. Twenty cases at the time of first lumbar puncture had no cells, and the highest had 1,480 cells. The average for all cases showing definite cell increase was 155.4 cells. In 41 cases the type of cell was of the lymphocyte variety, while in 47 polymorphonuclear cells predominated. In 3 instances the cell types were equally divided. Polymorphonuclear increase was frequent in those cases showing marked cell increase.

We have been interested in protein increase as a sign of central nervous system involvement, and have reported as poliomyelitis 39 cases in which protein increase was the only spinal fluid finding indicative of the disease, 6 of which showed typical cell increase later. Our reasons for reporting such cases seem to us sufficient. Very early in our experience we observed a case with marked paralysis of the face and arm in which protein increase was noted without increase in cell count. We note that Levinson [2] has recently reported 5 cases with muscle weakness in which there was no increase in cells, to which 5 cases we are glad to add 11 more. It is, of course, to be supposed that we have certified no case

TABLE IV

SPINAL FLUID ANALYSIS

Number of Cells	Number of Cases	Cell Type			Globulin				
		Pmn	Lymph	Equal	Normal	1+	2+	3+	4+

as poliomyelitis, with protein increase as the only spinal fluid finding, that was not supported by adequate symptoms and signs of the disease. It is felt that too little emphasis has been placed on the possible absence of cell increase in poliomyelitis. This feeling has been voiced by other writers.[3, 4, 5, 6] Meals and Bower,[5] have pointed out the error of current medical opinion on this point and have reported a series of cases in which 12.8 per cent had a normal cytology in the spinal fluid, yet showed characteristic neurological findings.

It is realized that protein increase and abnormal cytology have been observed in numerous types of illness. When poliomyelitis is occurring in epidemic proportions these same conditions are not infrequently erroneously classed as examples of this disease.

As a further check in the finding of increased protein in the spinal fluid, we have to date studied 25 patients not suspected of having poliomyelitis. On account of the ease of securing specimens we selected for this group surgical patients receiving spinal anesthesia. Sixteen showed negative spinal fluid findings. Of the 8 showing positive globulin, 1 was found to have a cord tumor; another had previously been diagnosed syphilis of the central nervous system, and showed cell increase as well as protein increase; a third gave a definite history of poliomyelitis within the week preceding the onset of appendicitis; 1 other case had positive serology of syphilis. In 4 instances we were unable to account for increased protein unless the following surgical conditions can be held accountable: acute appendicitis with migraine, carcinoma of the cecum, ruptured appendix, and inguinal hernia.

Spinal fluid sugar determinations were made in 69, and chloride determinations in 50 instances. In no case did these findings suggest some other disease. The average sugar content was 59 mg. per 100 c.c., and the average chloride content was 584 mg. per 100 c.c. of spinal fluid.

In Table V are listed a group of cases all of which had normal cytology in the spinal fluid at the time of the first puncture. It will be noted that in 15 lumbar puncture was done within 24 hours of the onset, and in 11 within 48 hours. The symptomatology differed in no way from other cases which we have observed. Protein increase was present in all but 3 at the time of first puncture.

MORTALITY

Death occurred in 3 patients, 2 as the result of bulbar paralysis, and 1 from pneumonia following a prolonged stay in a respirator. A complete necropsy was obtained in the case reported below.

Hospital No. 118764. H. K., negro male child, 2 years of age, was admitted to the University of Virginia Hospital because of nausea and restlessness of 3 days' duration. Twelve hours before admission the child seemed weak and unable to stand.

Physical examination showed an acutely ill child. Respiration was labored and breathing abdominal. Drowsiness almost to the point of stupor was noted. There was nystagmus of both eyes in the horizontal direction. The throat was injected and a generalized lymphadenopathy was present. There was marked weakness of both legs and arms, more noticeable on the left side. Rigidity of the neck was not present. Knee jerks and ankle jerks were absent and abdominal reflexes could not be elicited. Other reflexes appeared normal.

Temperature on admission was 104° F., respiratory rate was 84 per minute, pulse rate 198. The blood showed 100 per cent hemoglobin, 4,400,000 red and 21,400 white cells. Differential

showed 69 per cent polymorphonuclears and 25 per cent lymphocytes, and one eosinophil. Lumbar puncture showed 372 cells with polymorphonuclears predominating. Pandy's was negative and Ross Jones's 1 +.

Death occurred 4 hours after admission, apparently as a result of bulbar paralysis.

We are indebted to Dr. Albert E. Casey, Associate Professor of Pathology at the University of Virginia, for the following necropsy and pathological report.

NECROPSY AND PATHOLOGICAL REPORT

Cultures of tissues from the spinal cord and from the heart were made in bile and broth. These were found to be sterile.

The gross anatomical findings in this case represent first an enormous enlargement of all lymphoid tissues in the body, particularly noticeable in the Peyer's patches and solitary follicles of the intestines, mesenteric, mesocolic, and retroperitoneal lymph glands. The spleen was enlarged, friable, and the splenic corpuscles unusually prominent. A small reddish nodule was seen on the tunic of one testicle. Small bright red, circular areas, several mm. in diameter, were scattered over the lungs, and there was congestion of the lungs on section. The vessels of the meninges were markedly injected; no discoloration of the cerebrospinal fluid was noted. On cut section there was marked injection of the gray matter, particularly in the cervical spinal cord, in the medulla, areas of the pons, thalamus, lenticular caudate nuclei, but not prominent elsewhere.

The microscopic findings show an enormous enlargement of the germinal centers of lymph follicles throughout the body with diminished mitoses, increased masses of monocytes and endothelial cells and clasmatocytes, with occasional areas of focal necrosis. The peripheral mantel of small lymphocytes was much diminished and in many instances could with difficulty be found. This change involved the lymph follicles of the spleen (splenic corpuscles), of all lymph nodes, solitary follicles, and Peyer's patches. The reticulo-endothelial cells in the lymph sinuses were markedly increased in numbers and occasional neutrophils and eosinophils were seen. The interstices of the lungs were thickened with edema and considerable exudates of monocytes and neutrophils. The pulmonary alveoli were very little affected. The perivascular and lymphatic spaces throughout the body in all tissues showed scattered neutrophils, monocytes and eosinophils. In the meninges, particularly in the thoracic, cervical, and medullary areas, there were moderate numbers of monocytes and neutrophils, the former predominating. The perivascular spaces of the cord, medulla, thalamus, cerebellar nuclei, lenticular and caudate nuclei showed masses of neutrophils and monocytes, the change being possibly most marked in the pons and medulla, and diminishing distally from this area. There were a few small foci of monocytes and neutrophils in the gray matter of the cord or nuclei, not apparently related to the blood vessels. Scattered ganglion cells showed basophilic cytoplasm and hyperchromatic nuclei. Occasional dead cells were noted. In the cord, individual fibers and bundles of fibers show considerable swelling of the myelin. Anterior and posterior portions of the cord and brain were equally affected. The lateral cerebral hemispheres, ventricles, and choroid plexus were little affected. Occasional neutrophils and monocytes were present in the perineural lymph spaces of peripheral nerves. The liver showed a diffuse cytoplasmic fatty change, more prominent near the central veins. No areas of focal necrosis.

In conclusion, the change is that of a generalized infection marked by an exudate of reticulo-endothelial cells of monocytic and clasmatocytic types, of neutrophils and eosinophils. The lymphoid tissues, the interstices of the lungs, the lower cerebral and upper spinal segments being most affected.

RECOVERY OF VIRUS

The spinal cord was placed in glycerine and forwarded to Dr. Charles Armstrong at the National Institute of Health. He recovered a strain of virus capable of causing paralysis in monkeys. This, in so far as we are aware, represents the only instance of the recovery of a virus strain from a case of poliomyelitis in Virginia or North Carolina.

ESTIMATED INCIDENCE IN CHARLOTTESVILLE AND ALBEMARLE COUNTY

Charlottesville and Albemarle County have a population of 42,000. We estimate that 1,500 cases of poliomyelitis

have occurred in the city and county. It seems hardly possible that the University Hospital clinics could have received more than one-tenth of the total number of people affected. The mildness of the recent epidemic lends support to this assumption, and conversations with various physicians further convince us that our estimate is conservative. Numerous physicians admit having seen 50 or more cases presenting symptoms and signs identical with those we have described. The majority of these physicians, having profited by a first experience with poliomyelitis, as have the writers, feel that their patients represented true cases of this disease, although reports of only a few of their cases will be found in the records of our State Health Department. The reasons for failure to report need not be discussed at this time. If the disease here described is poliomyelitis, we must admit a morbidity out of all proportion to previous ideas as to its incidence.

A morbidity rate such as we have described is certainly not in accord with our previous conception of this disease. Figures concerning the morbidity rate of past epidemics of poliomyelitis are largely those of state and federal public health agencies. We are inclined to believe that they do not tell the whole story and that perhaps past epidemics have had associated with them a large number of non-paralytic cases which have never come to the attention of the medical profession. Due to the activities of a very energetic corps of field nurses we have had the opportunity of observing a large number of mild cases, so mild in many instances that they would ordinarily not have sought the services of a physician.

Just how misleading statistics on this subject may be is well illustrated by the following comparison: During the past spring and summer 647 cases of poliomyelitis were reported to the Virginia State Health Department, 191 of these from Charlottesville and Albemarle County. Questionnaires on these 647 cases were productive of 525 answers. Of these 525, 271 had suffered some degree of muscle weakness, and 254 were reported as non-paralyzed, a paralysis rate of 51 per cent. Among the answers received were 191 from Charlottesville and Albemarle County which reported 28 paralyzed and 163 non-paralyzed cases, a paralysis rate of 14 per cent, as compared to 51 per cent for the state at large. Excluding the cases from Charlottesville and Albemarle County, the paralysis rate for the remainder of the state is 72 per cent. If the disease described by us is poliomyelitis it must be admitted that our state statistics can hardly be of any real value in so far as any comparative study is concerned.

The discrepancy can in a large measure be explained by confusion in the medical ranks and the reporting of only paralyzed cases. The reporting of paralyzed cases alone gives no reliable index of the incidence of poliomyelitis in any city or state, and the quarantine of a few paralzed individuals accomplishes little in the way of public protection. Once poliomyelitis becomes entrenched in a community it is doubtful if any system of quarantine can be effective. It would seem to us necessary that we change many of our present ideas concerning quarantine of and the reporting of cases of poliomyelitis.

The very prevalence of the disease together with the low rate of paralysis have been the two features which have led many careful physicians to refuse to admit any unusual occurrence of poliomyelitis in this state, or to advance the idea that we have been dealing with a virus disease other than poliomyelitis, or that we have been dealing with poliomyelitis in addition

to some other disease occurring in epidemic proportions. It is well known that poliomyelitis is a protean disease and that past epidemics have differed one from the other in many particulars. All previously recorded epidemics have had in common certain symptoms and signs which make it seem proper to class them as examples of one and the same disease. The same can be said for the disease that we have described, and until there is adequate proof that we have been dealing with a new and previously unreported condition, we prefer to consider our cases as examples of poliomyelitis. We have seen recently a sufficient number of mild cases confirmed by spinal fluid findings to incline us very strongly to the view advanced by Paul and Trask [1] and others, that certain "characteristic types of minor illness which accompany an epidemic of poliomyelitis, probably represent mild cases of the disease."

It is to be regretted that some serious study attempting to prove or disprove an epidemic of poliomyelitis in this state has not been undertaken. If a new disease can be proved the writer will feel grateful for the opportunity of having observed and studied after a fashion a considerable number of patients so affected.

CONCLUSIONS

One hundred and eleven cases have been described which have had sufficient similarity to previously reported epidemics to stamp as poliomyelitis a recent outbreak of disease occurring in Charlottesville, Va., and adjacent territory. Laboratory data and clinical evidence are supplied which warrant the assertion that in epidemic times normal cytology is no proof that the case in question is not one of poliomyelitis. The finding of increased protein in the spinal fluid is of great diagnostic value and in this series, for practical purposes, has been a constant finding and a very material aid in the diagnosis of early cases.

We cannot consider poliomyelitis solely in terms of its neurological manifestations as is the current medical tendency. We think it proper to consider it as a systemic disease with neurological manifestations in the majority of instances. To think otherwise precludes the probability of diagnosis of early abortive and nonparalytic cases and interferes very materially with a proper conception of its probable incidence.

We are unable to suppose the presence of a new disease, as has been frequently suggested, and feel that this thought may well be the natural reaction of many physicians experiencing for the first time an epidemic of poliomyelitis in all its manifestations. The low death rate and the infrequent occurrence of muscle weakness and paralysis suggest the hope that poliomyelitis may be fast becoming a less malignant disease.

Results of Field Studies With Poliomyelitis Vaccine*

A. G. GILLIAM AND R. H. ONSTOTT

Assistant Surgeon; and Passed Assistant Surgeon, U. S. Public Health Service, Washington, D. C.

DURING the past year lay and medical interest in vaccination against poliomyelitis has been much aroused. With the advent of the 1935 poliomyelitis season it became evident that this interest would be translated into fairly widespread use of the proposed vaccines as prophylactics for the disease. It appeared to the Public Health Service that there was insufficient evidence to justify any general recommendation of them as prophylactics. On the other hand, the vaccine prepared by Dr. Brodie appeared on theoretical and experimental grounds to be reasonably safe, and seemed to offer some hope as a preventive. Realizing that its use would probably be rather extensive, it was felt worth while to observe its application in controlled studies designed to determine its efficacy in preventing poliomyelitis under field conditions. So far as we are aware no such rigidly controlled clinical study has been undertaken to evaluate this, or any other vaccine. It was fully appreciated that the chance of reaching a definite conclusion was slight, and was dependent upon the subsequent development of a sharp outbreak of the disease in the study area, but it was believed that such an attempt should nevertheless be made.

On May 30 one of us arrived in Raleigh, N. C., at the request of the State Health Department. After consultation with officials of the department it was decided to offer assistance in vaccine studies in communities not then involved in the beginning outbreak. For reasons of administrative convenience urban centers were desired as study points rather than rural areas.

It also seemed desirable to avoid communities in which there was already an unusual incidence of poliomyelitis, in order to reduce the risk of vaccinating individuals in the incubation period of the disease.

Because of particular interest shown in Greensboro by 2 practitioners and the health officer, Dr. C. C. Hudson, this city was selected as the first center for the trial. Greensboro was about 80 miles west of the heavily infected focus, but since the epidemic began early in the poliomyelitis season, it seemed reasonable to suppose that Greensboro would eventually be involved. Dr. Hudson arranged a meeting of the physicians there and the proposed study was thoroughly discussed.

It was desired to use the vaccine under conditions simulating those under which it would ordinarily be used except that the choice of individuals to receive it be uninfluenced by any

* Read at the Fourth Annual Meeting of the Southern Branch, American Public Health Association, in St. Louis, Mo., November 19, 1935.

factors which could conceivably affect the results, and the follow-up on the vaccinated and unvaccinated be coördinated. The patient-physician relationship was maintained.

Dr. Hudson and the local medical society prepared a statement (approved by one of us) offering the vaccine to the public in the following manner:

The vaccine was offered frankly for study purposes—to determine its efficacy in preventing poliomyelitis under field conditions. It was considered as offering hope as a prophylactic and as being reasonably safe. Parents desiring vaccine for their children under 8 years of age were instructed to list name, address, age, color, and sex with their own physician. The physicians' lists would then be turned over to one of us who would arbitrarily divide them so that approximately half would receive vaccine and half be held as controls. It was made clear that the private physician would have no voice in this selection. The inoculations were to be done in the physicians' offices during office hours and those selected would be notified by us when to report for vaccination. No effort was made to urge vaccination, or to urge physicians to recommend it.

Lists were first received from physicians during the third week in June. The method of selection employed was alphabetical. The names of applicants were arranged alphabetically and approximately the last half of each list was selected for vaccination, the first half being held as controls.

The physicians had some hesitancy in administering the vaccine and an effort was made for one of us to be present with each physician to assist in his first inoculations.

With the announcement of the Greensboro study, Dr. Brodie, who coöperated fully not only in supplying the vaccine but in every other manner possible, simultaneously discontinued sending vaccine to North Carolina except at our direction. Requests received by him from individuals and physicians were submitted to us. The requests coming through him, and those received directly from physicians in other parts of the state, were numerous, and much pressure was exerted on us by some physicians for vaccine for their children. These were uniformly refused with the statement that vaccine used under our supervision would be used only in controlled studies. Where possible we visited localities from which many requests were received, and because of such requests Wilmington and Washington, N. C., with the coöperation of the Health Officers, Dr. A. H. Elliott and Dr. D. E. Ford, were later selected for study sites. These were the only places in North Carolina offering the opportunity for such study.

A number of communities in Virginia requested that they be selected as study sites. In 6 of these places the problem was discussed with the health officers and physicians and the décision was reached that it was too late to attempt any work. However, in Petersburg, arrangements were made with the physicians and the Health Officer, Dr. Mason Romaine.

The same general procedure followed in Greensboro was used in these areas except that, profiting by the Greensboro experience, a time limit of 1 week was set for listing names; the upper age limit was raised to 10 years in Petersburg; and the administration of the vaccine was demonstrated to physicians as a group rather than by giving assistance to each individually.

In the 4 localities, 1,452 individuals, representing 7.2 per cent of the population of the ages involved, requested vaccine, of whom 766 were selected by the method described to receive it, and 686 were held as controls. Of the 766 selected, only 458 reported

for inoculation, representing 2.3 per cent of the child population.

Various methods of inoculation and various inoculation sites were used by individual physicians. Dr. Brodie has recommended 1 to 2 c.c. given intracutaneously, and the remainder of a 5 c.c. dose subcutaneously at each of the two dates of injections given 14 days apart. For uniformity of dosage we recommended 1 c.c. intracutaneously and 4 c.c. subcutaneously.

To avoid pain from the injection of such a large volume of vaccine, prior use of 0.5 per cent to 1.0 per cent novocaine was at first recommended. This was given up because the increased quantity of material necessarily injected in a small area, and the extra introduction of the needle seemed to outweigh the advantages of the novocaine.

Following Dr. Brodie's advice, it was recommended to administer the second dose on the 14th day following the first. Of the 458 inoculated, 422 received 2 doses and 36 only 1. Of the 422 receiving 2 doses, 326 (77 per cent) had their second dose on the 14th day; 16 (3 per cent) less than 2 weeks from the first; 70 (17 per cent) in the 3rd week, and 10 (2 per cent) over 3 weeks following the first dose.

Of the total number inoculated, 1.3 per cent were under 1 year of age; 48.9 per cent 1–4 years, and 49.8 per cent 5–10 years of age. Negroes comprised 16 per cent of those receiving vaccine.

REACTIONS

Physicians administering the vaccine were requested to record all local and general reactions. However, to make the observations uniform we attempted to see the vaccinated children at about the time of the second dose and about 1 month following it. At these visits inquiry was made regarding reactions; the inoculation sites were examined where possible; and inquiry was made regarding symptoms which might have represented unrecognized abortive poliomyelitis. Such visits were completed in 88 per cent of the vaccinated. Inquiry was also made in 71 per cent of the controls as to symptoms which might have resulted from unrecognized abortive poliomyelitis. This was in addition to the routine reporting by the physicians of all cases of suspected poliomyelitis to the health officer.

It was found that such follow-up visits were necessary to secure an estimate of the reactions. Either because the physicians' findings were not recorded, or because they did not see the patients again after vaccination, many reactions were noted only by means of our follow-up visits. For example, there was no note on the physicians' cards of 6 of the 14 abscesses which occurred. It also developed that 3 children recorded as receiving the vaccine had not been inoculated and that 4 controls had been inoculated with no record of the vaccinations given us. (These and 6 other controls inoculated and recorded are not included in the study group.)

On the basis of our records in the 403 vaccinated seen by us, and the physicians' records in 55 cases not seen by us, 229 individuals (50 per cent) were found to have had local reactions consisting of one or more of the following conditions:

a. Redness and swelling 1 inch or more in diameter and lasting longer than 48 hours
b. Local pain lasting longer than 48 hours
c. Local suppuration or necrosis
d. Induration lasting 3 weeks or longer

In the Greensboro series, where reactions occurred more frequently than in the other areas, reactions followed 48 per cent (178 out of 374) of the inoculations preceded by novocaine and in only 17 per cent (11 out of 64) of those not preceded by novocaine.

No novocaine was used in the other localities.

In the 4 study areas, 458 individuals received 880 inoculations—458 first doses, and 422 second doses. Local reaction of some degree followed 24 per cent (110) of the first inoculations, and 43 per cent (181) of the second.

As a group, the reactions from the second dose were generally more severe than those from the first although the doses were the same in amount. There was no correlation between local or general reactions and the time interval between the 2 doses.

Two children who had had antirabies treatment in the summer of 1934 had no local or general reaction following the Brodie vaccine.

Of the local reactions recorded, only 15 were out of the ordinary. One of these was a fairly severe urticaria occurring around the site of the subcutaneous inoculation on the 7th day in a child with an allergic history. Ten were abscesses at the site of the subcutaneous inoculation that were opened surgically or opened spontaneously, and 4 were fluctuant masses 1 to 2 inches in diameter which had not opened. Most of the abscesses cleared up promptly following drainage and local treatment; however, several were very slow to heal, the area filling in with indolent granulation tissue. There were also 15 instances of superficial slough 3 to 5 mm. in diameter at the site of the intracutaneous inoculation.

General reactions following the vaccine were observed in 17 children (3.7 per cent) and in 4 of them were, at the time, very disturbing. Résumés of the histories of these 4 are as follows:

1. Within 30 seconds after the administration of her first dose, a white female, 2 years of age, fainted, became cyanotic, and stopped breathing. After 10 to 15 minutes of manual and mouth-to-mouth artificial respiration she recovered and suffered no further ill effects. She had no reaction following the second dose.

2. On the 3rd day after vaccination, a white female, 5 years of age, developed what was diagnosed as an acute inflammatory rheumatism of both knees. She had high fever for 3 days, and was confined to bed for 10 days. When seen 3 weeks following vaccination, her knees were still swollen but not tender, and the child was extremely weak and underweight. Seen again 7 weeks after inoculation she had gained weight and strength and suffered no apparent disability. The second dose was not given.

3. About 10 minutes after the first dose, a white male, 5 years of age, felt faint, nauseated and became very pale. He had a "medicine taste" in his mouth. After lying down 30 minutes he felt all right. His parents state he now has no appetite, has lost weight and strength, and appears anemic and listless. He was not given the second dose.

4. A white male, 6 years of age, complains of occasional cramping pain in the leg, the site of the second subcutaneous inoculation. One month after vaccination these cramps are less frequent and less severe but still occasionally present.

An additional 13 children had fever of 101–104° for 1 to 2 days and were listless. Several of them had headaches and were nauseated. In 10 of these the fever occurred in the first 3 days. In the other 3 it was associated with abscesses and subsided when they opened.

GENERAL DISCUSSION

The evaluation of the efficacy of a vaccine against poliomyelitis introduces problems peculiar to any disease carrying a low morbidity rate and factors inherent in human nature itself. The sample of the population tested must be adequate enough, in point of numbers, to satisfy elementary requirements of the theory of probability. It must also be a good sample—"fairly representative qualitatively of the universe from which it is drawn." To get a good sample is primarily and

fundamentally a biologic problem and one which may involve intangible elements not easily susceptible to statistical treatment. It is usually relatively simple to obtain a good sample in regard to such variables as age, sex, race, and geographic location, or it is possible to correct for any discrepancies in these factors which may develop. It is impossible to determine what selective influences make one individual apply for a vaccine and another not apply; and further impossible to know what effect these factors might have on the results.

For example, 1,452 persons applied for vaccine. Following the receipt of applications, 15 cases of poliomyelitis were reported in other children of the same age in the same communities. The rate these cases represent out of the total child population, applied to the 1,452 applicants, gives an expectancy of 1.09 ± 1.03 cases among those in the study group. In other words, one would have expected the chance occurrence of from 0 to 2 cases in the study group. Actually, no cases were reported. The figures are too small for much significance but they make one wonder if people who applied for vaccine in this series, regardless of whether they were vaccinated or not, were not somehow less likely to acquire poliomyelitis than other individuals in the same communities.

It is therefore also obvious that the sample of population vaccinated should be adequately controlled with an equally large group of unvaccinated. It is not enough to vaccinate all applicants and retain as controls other children in the same community who did not apply. The division of the applicants into vaccinated and controls must be impartial.

The adequacy of the sample, in point of numbers, to satisfy elementary requirements of the theory of probability is amenable to calculation. In North Carolina counties where the studies were carried out, assuming that the attack rate observed this summer (approximately 60 cases per 100,000 of the population under 8 years of age) prevailed in the controls, and that the vaccine was 100 per cent effective, a sample of 20,000 candidates—10,000 vaccinated and 10,000 controls—would have been necessary in order that the difference between the number of cases in the vaccinated and the number in the controls be relatively free from mere chance. With the same rate in controls, and the vaccine only 80 per cent effective, a sample of 40,000 candidates would have been necessary. Of course, the inclusion of individuals of older ages in the study group would tremendously increase the size of sample required because of the sharp decline in attack rate as age progresses. The above figures are also predicated on reported cases, about 15 per cent of which were abortive. For an unequivocal evaluation it would probably be more rational to use only paralytic cases because of diagnostic difficulties and because paralysis is, after all, what it is desired to prevent. The sample necessary would be increased if it were calculated on the basis of the paralytic rate.

Selection of vaccinated and controls by the method used in these studies is, so far as we are aware, open to only one serious scientific criticism. Of the 766 selected to receive vaccine, only 458 reported for inoculation. We have no way of knowing how many of the controls, had they been selected, would have refused the vaccine. It must be stated, however, that in any method of using arbitrarily selected human controls, constant vigilance and supervision by an impartial observer appears necessary. Methods of circumvention of the rules set down are numerous, and for adequate studies must be carefully guarded against.

It therefore appears that the considerations brought out in this study—psychologic, administrative, and scientific—present problems which in the aggregate make the unequivocal evaluation of the efficacy of a poliomyelitis vaccine a matter of extreme difficulty.

SUMMARY

1. The administrative procedures employed in conducting field trials of the Brodie poliomyelitis vaccine in North Carolina and Virginia during the summer of 1935 have been outlined.

2. In the 4 study areas, 1,452 applications for vaccine were received, of which 766 were selected for vaccination and 686 held as controls. Four hundred and fifty-eight of those selected were inoculated, 422 with 2 doses and 36 with 1 dose. In addition, 10 controls were known to have been inoculated. No cases of poliomyelitis were reported in any of the 1,452 candidates, and hence no conclusions concerning the efficacy of the vaccine can be reached from this study.

3. Local reactions occurred in 50 per cent of those inoculated but were not of serious import except in 3 per cent (14 abscesses).

4. General reactions were observed in 17 instances (3.7 per cent), 4 of which were temporarily very disturbing.

5. In an area where the controls were as much spared from epidemic prevalence as were the children of the North Carolina counties where these studies were carried out, and with all possible safeguards as to impartial division of applicants, 10,000 vaccinated children, together with 10,000 controls would have been necessary to show conclusively the value of a perfect vaccine against poliomyelitis.

If the vaccine were only 80 per cent effective, a total of 40,000 children would have been necessary.

ACKNOWLEDGMENTS—The coöperation of Dr. Park and Dr. Brodie, the State Health Departments of North Carolina and Virginia and the health officers, physicians and public of the study areas, is gratefully acknowledged. It is impossible for one not implicated to appreciate the difficulties imposed on the health officers and the private physicians coöperating in a study of this sort.

The general planning and supervision of these studies were under the direction of Dr. J. P. Leake, Medical Director, U. S. Public Health Service.

Rat Extermination

IT has been called to the attention of the *Journal* that—". . . two men, R. N. and H. A. Ferris, brothers, the former in the early 20's and the latter about 30 years of age, are apparently touring the country offering to put on campaigns of rat extermination. They carry with them credentials which appear to be authentic as well as newspaper clippings endorsing the work. Their method of procedure seems to be to establish an alliance of some kind with local health departments. The plan that they outline for their campaign of extermination as well as the materials used are above reproach and would probably win the endorsement of any health official. Unfortunately, however, after operating for a term of several weeks and making as many collections as possible, the gentlemen above mentioned seem to have developed a habit of disappearing without leaving a forwarding address. By accident the writer was able to uncover the home of these gentlemen and a registered letter with return receipt requested was addressed to one of them, requesting a statement as to their intentions for completing the work which they had undertaken locally. The receipt has returned, but to date no reply to the letter."

Active Immunization Against Poliomyelitis*

MAURICE BRODIE, M.D., F.A.P.H.A., AND
WILLIAM H. PARK, M.D., F.A.P.H.A.

New York University; and Bureau of Laboratories, Department of Health, New York, N. Y.

FOR the past 5 years, we have carried out experiments with a view toward developing a safe and effective method of immunization against poliomyelitis. In this paper, we propose to give a report of our approach and to present the data collected up to the present time.

Using *Macacus rhesus* monkeys, three methods were tried. These included the use of sub-infective doses of active virus, virus-serum combinations, and germicidally inactivated virus.

The use of active virus was, as one would expect, the most effective, but it proved dangerous, for some of the animals developed the disease during the course of immunization. Since, neither in poliomyelitis nor in other virus diseases is there any evidence for the belief that the virus loses its infectivity for man through animal passage, it was not deemed advisable to try it in the human.

Virus-serum combinations produced immunity but were difficult to standardize.

Therefore, germicidally inactivated virus was resorted to, inasmuch as the experiences of Bedson [1] and others with the viruses of herpes, psittacosis, fowl-plague, foot and mouth disease, and rabies, indicated that after chemical treatment, immunization could be obtained with non-infective preparations, whereas heat killed material was ineffective.

In a recent article Flexner [2] maintained that there was no evidence to show that germicidally inactivated virus engendered immunity. However, he refers to experiments involving too few animals to be significant. Moreover, in that work no significance was attached to the importance of treating the virus so as to render it non-infective, but not overtreating it. In our work it was found, in both monkeys and children, that when formalin acts upon the virus for the minimum amount of time necessary to render it non-infective, the material is superior to virus that is overtreated. This is in keeping with similar findings by Bedson and others for foot and mouth virus.[3] In fact, as we will point out, storage for more than 2 to 3 weeks at icebox temperature, which allows overaction of the formalin, renders the vaccine non-antigenic. Moreover, with germicidally inactivated viruses, as has been shown by the work of MacKenzie [4] and others, it is necessary to use large doses. In both monkeys and humans we found this to be the case in immunization against poliomyelitis.

With freshly prepared material, inactivated for just the proper length

* Read at the Fourth Annual Meeting of the Southern Branch, American Public Health Association, in St. Louis, Mo., November 19, 1935.

of time, and given in large doses, we have been able to demonstrate serum antibody in monkeys. Likewise, both Olitzky[5] of the Rockefeller Institute, and Schultz[6] of Stanford University have reported antibody production in monkeys with formalized vaccine. They failed to demonstrate any resistance to intracerebral inoculation with their test, which was more severe than we used for the demonstration of tissue immunity. We have reported that even large amounts of active virus given to monkeys immunized them against only small or moderate intracerebral doses of virus. The method for demonstrating such a fine degree of immunity has been to carry out simultaneous titrations of the virus in a series of 8 monkeys, putting 2 animals on each of 4 doses. The immunized animals receive 1 to 3 times the smallest amount of virus that produces complete paralysis in both monkeys in the usual incubation period.

When serums are tested, the neutralizing power is estimated as the number of minimal completely paralyzing doses that the serum neutralizes—many times the smallest dose that brings down the controls. That such a method gives reasonable accuracy is indicated from the following results of titration:

During the time the monkey experimental work was being carried out, 94 animals were used in titrating the virus. Of 60 monkeys which received the minimal, or 2 to 4 times the minimal, completely paralyzing doses, 57 came down with complete paralysis in the usual incubation period. Only 2 of the other 34, which received less than the estimated infective dose of virus, succumbed to the disease.

During the past 16 months, because of the large number of monkeys used, it has not been possible to keep them for a long enough time prior to inoculation to get them on uniform rations and to weed out those with intercurrent infection. As a result, the virus titrations have not been so constant, and, to offset this, sera are tested prior to receiving vaccine on 5 to 10 infective doses respectively, and multiples thereof. After vaccination the sera are tested against 40 and 80 infective doses and multiples thereof. The test for antibody in humans, therefore, is sufficiently coarse to meet the criteria of antibody in the hands of others.

Like Flexner, who has pointed out that there is no evidence to believe that monkey passage virus is non-infective for man, we have felt the use of non-infective material the safest procedure and therefore worthy of extensive trial to determine whether or not whatever immunity it produced would be sufficient to protect children against the disease. The safety of the vaccine is indicated by the fact that intracerebral and intraperitoneal inoculations have failed to infect monkeys. In addition, the formalin in the concentration used renders non-infective choriomeningitis, herpes, and other viruses, and so should render inert any chance virus the monkey may carry. We realize that should active immunization protect against the disease, it will not completely solve the problem of poliomyelitis because of the difficulty of vaccinating so many in the absence of a susceptibility test. However, we do not agree with Aycock and others who maintain that the procedure is unwarranted because of the relatively small number of susceptible individuals. To maintain that infection with the virus of poliomyelitis is a question of susceptibility entirely, is an assumption, as we will point out later.

Those most likely to contract poliomyelitis are children below 10 years of age. The greatest incidence of the disease is in the 1–5 year group and in the 6–10 year old group, which is in keeping with the larger proportion in these groups who show no antibody,

and the low average level of such a group. This is indicated in Table I where the amount of antibody is designated as none, where the 0.9 c.c. of serum neutralizes less than 10 infective doses of virus, slight amounts, where it neutralizes 10–50 infective doses, which is probably an almost negligible amount, moderate, neutralizing 50–200 infective doses; and considerable amounts in which more than 200 infective doses are neutralized. Thus it would seem that the lack of antibody is a factor predisposing to the disease inasmuch as over 85 per cent of those under 5, and over 70 per cent of the 6–10 year old group show no antibody or only a small amount of antibody.

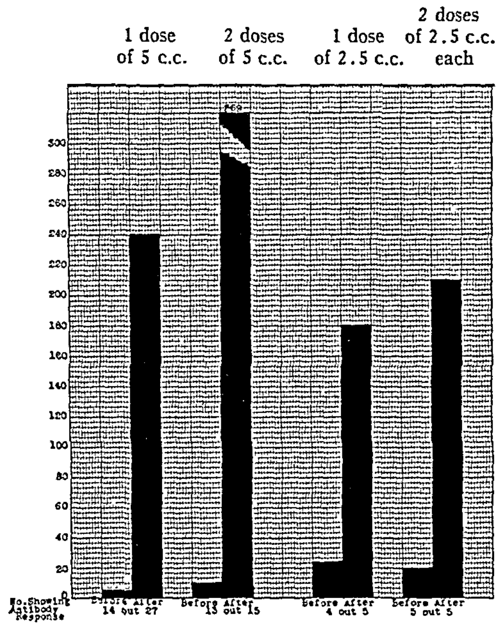
This does not explain why in an epidemic approximately only 1 of the 170 children under 5 showing no antibody, and about the same proportion of those under 10 develop the disease. This may be due to the individual non-specific variation in the susceptibility of the children, or the size of the infective dose, or number of exposures, or the accessibility of the virus to the olfactory fila.

Until these or other factors in the epidemiology of the disease are understood, then mass immunization, though wasteful, is a logical procedure.

IMMUNIZATION OF CHILDREN

This study consists of 2 parts, (1) the determination of antibody in approximately 150 children, and (2) field studies.

GRAPH I—Antibody Response to one and two doses—5 c.c. or 2.5 c.c.



ANTIBODY RESPONSES

These may be summarized as follows:

1. The immune response was proportional to the size of the dose tried for as Graph I indicates, with 5 c.c. doses the response was decidedly better than with 2.5 c.c. amounts.

2. As would be expected, where antibody was already present the response was decidedly better and in keeping with the amount of natural antibody present.

3. In the absence of any natural antibody, 60 to 65 per cent responded to a single, and nearly 90 per cent to 2 doses. Throughout, 2 doses gave a greater incidence, degree and duration of immunity than did 1 dose, as is indicated in Graphs I, II, III, *and* IV. *In* Graphs II and III are recorded the data collected from tests done on the serum of a small group of children at various intervals

TABLE I

NORMAL URBAN ADULTS

	No Antibody Neutralizes Less 10 M.C.P.	*Slight Antibody Neutralizes 10–50 M.C.P.*	*Moderate Antibody Neutralizes 60–200 M.C.P.*	*Considerable Antibody Neutralizes 200+ M.C.P.*	*Total*
6 mo.– 1 yr.	5	2			7
2 yr.– 5 yr.	54–62.8%	19–22.1%	11–12.8%	2– 2.3%	86
6 yr.–10 yr.	15–38.5%	13–33.3%	9–23.1%	2– 5.1%	39
11 yr.–17 yr.	0	1– 6.25%	5–31.25%	10–62.5%	16
Adults	1– 2.6%	2– 5.3%	6–16%	28–76%	37

after immunization. The group which received a single dose responded exceedingly well, but the antibody fell off rather rapidly so that in several children it had almost completely disappeared in 5-8 months. Following the administration of 2 doses the antibody produced was still present at 5-8 months in all the individuals tested and could be demonstrated in 4 out of 6 tested 1 year after immunization. Where 1 dose failed, a second often produced a response as indicated in Graph IV, where after a single dose no antibody developed in a child, but after the second considerable antibody could be demonstrated. Similar findings were obtained in 6 out of 7 children. When the antibody disappeared after a single dose, it sometimes responded rapidly to a second dose. Three children from whose serum the antibody had disappeared within 6 months after the first dose were given a second dose, and a fourth child was given a second and third dose. All showed considerable antibody which persisted for a longer time than after the first inoculation.

Upon using brain stem as well as cord for preparation of the vaccine it was inactivated in a shorter period of time. Several series of children were given different batches of vaccine incubated with formalin for different periods. Although the groups were small, the results given in Graph V indicate that with the longer exposures to formalin less antibody develops.

The vaccine does not keep well in storage. It was shown both in humans and monkeys that after storage for 1 month the vaccine produced but little antibody, and that after 2½ months at icebox temperature no antibody response could be demonstrated. It is interesting to note that at Seaview Hospital, New York, 1 of 4 children given vaccine which had been stored for 2½ months and who showed no antibody after immunization, contracted poliomyelitis. At this institution none of the 39 children given freshly prepared material developed the disease, whereas 1 of the non-vaccinated children came down.

Antibody can be demonstrated about 1 week after injection and reaches its height in 3 to 4 weeks. Therefore, no protection can be expected unless the person has received the vaccine at least 3 weeks prior to exposure. Thus, the

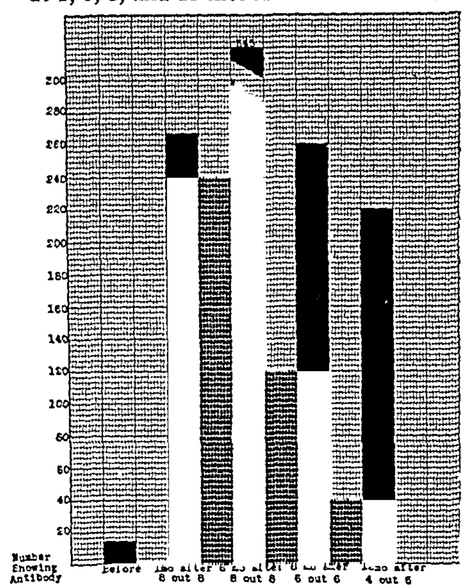
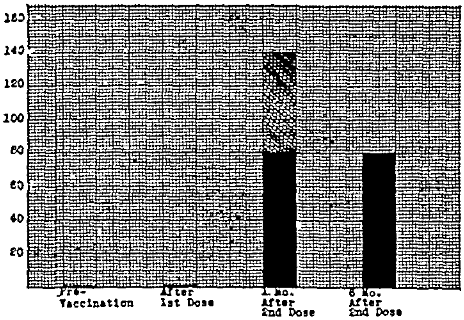


GRAPH IV—One Dose—No Response. A Second Dose—Antibody Response

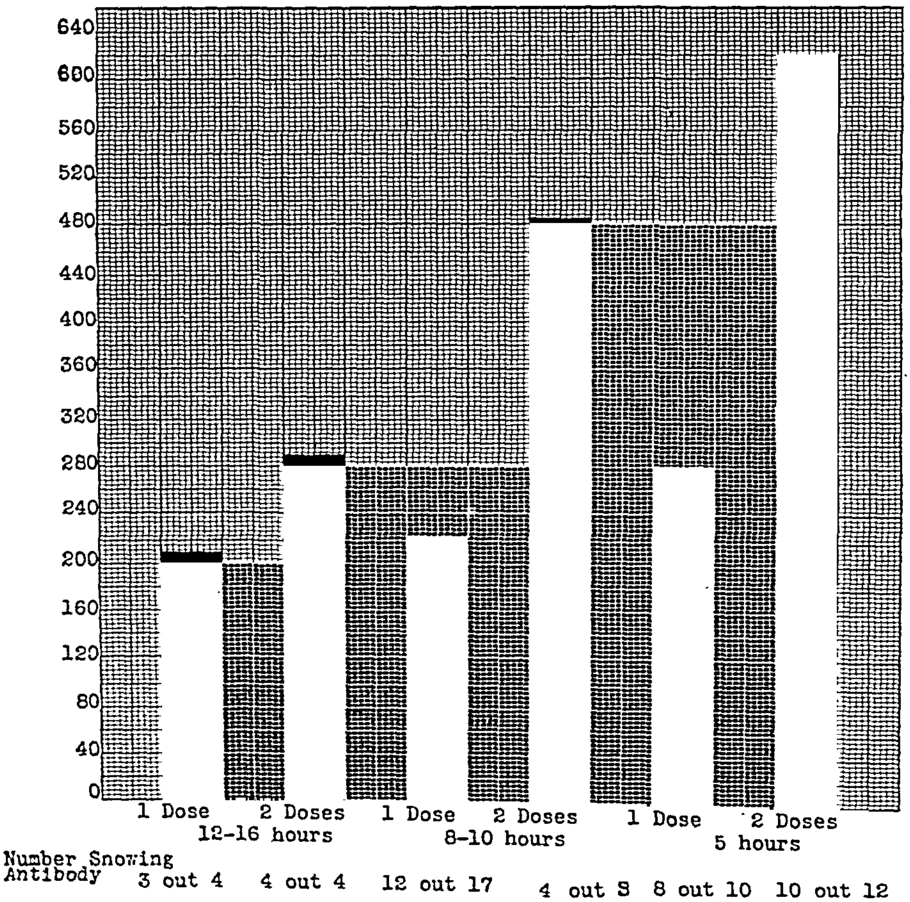


vaccine will be of no value where exposure has already taken place.

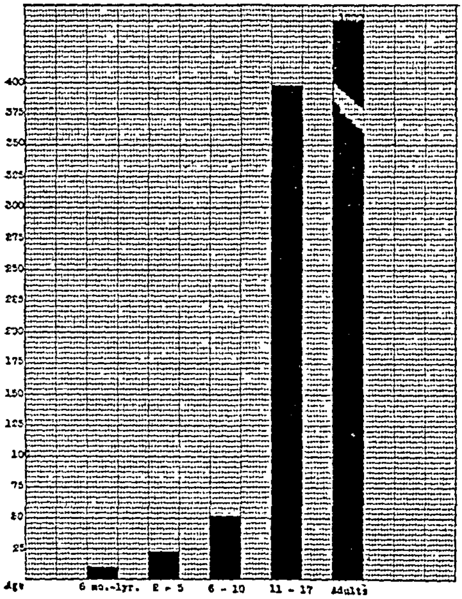
FIELD STUDIES

Up to the present more than 9,000 individuals have received vaccine. Inasmuch as more than 7,000 of these were in endemic or epidemic foci, it is quite likely that they were exposed to the virus. The control group, of non-vaccinated children consists of about 7,500. Of these approximately 4,500 were in exposed areas and can be compared with the similar group of 7,000 vaccinated. In so far as possible each vaccinated individual was matched with a control in the same district and of the same age. Wherever possible playmates were used. The details of the method of control have been discussed previously. Less than 1 per cent of those given the vaccine developed a general reaction. In cases where reaction did occur, it usually passed off in less than 24

GRAPH V—Antibody Response to Various Periods of Inactivation in Children with Little or No Pre-vaccinal Antibody



GRAPH VI—Antibody Levels in Normals



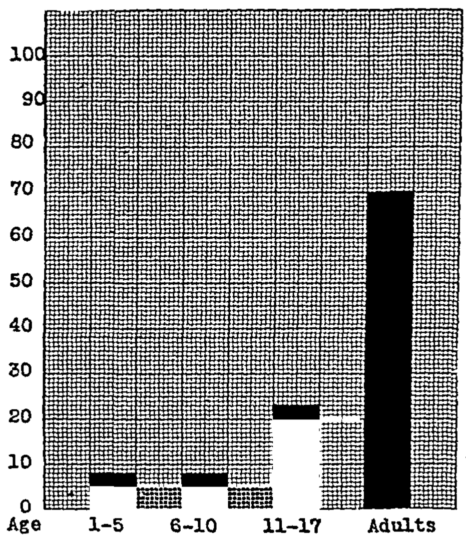
hours. About 2 per cent had local reactions such as induration and slight superficial necrosis, or occasionally a small abscess.

The vaccinated group included 564 individuals who were vaccinated after a definite history of exposure. Three of these developed the disease on the day of injection, and 1, 13 days later. The latter developed as a fulminating bulbar case. Inasmuch as it takes at least 3 weeks to obtain the full response from the vaccine, one cannot expect protection after exposure.

Of those vaccinated prior to exposure the largest groups were in North Carolina; Kern County, Calif.; and at the Los Angeles County hospital. The first group will be reported upon in detail by Dr. Gilliam. The second group has been reported on by Drs. Joe Smith and M. A. Gifford in their annual report, at which time somewhat over 3,000 had received vaccine. Nearly an additional 1,000 have since been injected. None of those vaccinated after exposure contracted the disease.* Dr. Emil Bogen, in reviewing the statistical data, states that, judging from the general incidence of the disease, one would have expected 3 to 5 cases to occur in the vaccinated group. In the town of Taft, where 652 were vaccinated and controls set up, 2 in the control group contracted the disease. Of the 200 on the staff of the Kern County hospital who received the vaccine, none contracted the disease, although the incidence was high among attendants of neighboring hospitals, such as those of Los Angeles County, Orange County, and Fresno County. Since all of the hospital staff were vaccinated, there were no controls for evaluating the vaccine.

At the Los Angeles County Hospital, where more than 300 nurses and physicians were vaccinated, Dr. Kessel reported that in one group of 42 vaccinated (15 received Kolmer vaccine) none came down with the disease, whereas 3 of the control group of 50 contracted poliomyelitis.

GRAPH VII—Antibody Levels in Poliomyelitis



* We have recently learned of a case developing 13 days after a single dose. A similar second case has only been reported, but the diagnosis is not certain.

DISCUSSION

These studies have brought out the fact that a formalized vaccine produces some antibody in both monkeys and humans. That antibody is an indication of some real immunity is based upon the following evidence:

1. In keeping with the findings of others, we have shown that the incidence and degree of antibody (Table I, Graph VI) increases with age, which correlate with the lower incidence of the disease in the higher age groups, so it would appear that the presence of this antibody is a factor in protecting older children and adults from the disease.

2. In comparing the immunity developed after the injection of active virus with that following the administration of formalized virus, it was found that with living virus the degree of both tissue and humoral immunity was higher.

3. The antibody content of a group of paralytic poliomyelitis cases was tested during the first week of the disease and compared with that in normal individuals. The presence and amount of antibody were compared for different age groups. It was found in the small group tested that persons with acute poliomyelitis usually had little or no antibody. Inasmuch as the level of antibody seems decidedly lower in poliomyelitis than in so-called normal individuals, as demonstrated in Graphs VI and VII, we feel that the lack of specific antiviral substance is one of the determining factors that predisposes individuals to poliomyelitis.

When the virus enters the nose, the antibody present in the nasal secretions, if in sufficient quantity, may neutralize the virus. Should this, the first line of defense, fail, then the virus can get to the central nervous system, where it may or may not multiply, depending upon the resistance of the cerebrospinal axis.

The combined humoral and tissue immunity of children can be tested only in following up the outcome of natural exposure. Up to the present, none * of nearly 7,000 who were probably exposed, after vaccination with fresh vaccine was completed, have contracted the disease, whereas 5 of a smaller control group have come down.

The field trials must continue on a still larger scale to give the final answer. We feel that further work in this direction is merited because:

1. The vaccine is non-infective upon intracerebral inoculation into monkeys and from all experiences to date appears to be harmless.

2. Some immunity is developed and although evidenced only as antibody production, we have indicated its importance in the mechanics of protection.

3. Immunization against other virus diseases such as rabies, encephalomyelitis and louping-ill, has been obtained under field conditions with similar types of vaccine.

CONCLUSIONS

A formalized poliomyelitis vaccine which fails to infect monkeys after intracerebral inoculation and so probably is safe, stimulates antibody.

The present inadequate data have been favorable, and do not show that the vaccine does not immunize.

Field studies on at least 50,000 more children should continue in order to reach a positive evaluation.

* We have recently learned of a case developing 13 days after a single dose. A similar second case has only been reported, but the diagnosis is not certain.

Vaccination Against Acute Anterior Poliomyelitis*

JOHN A. KOLMER, M.D., D.Sc., LL.D.

Professor of Medicine, Temple University, and Director of The Research Institute of Cutaneous Medicine, Philadelphia, Pa.

BEING convinced by reasons fully discussed elsewhere [1] that effective vaccination against acute anterior poliomyelitis requires the administration of active virus, I have employed as a vaccine for the immunization of monkeys and human beings a 4 per cent remote monkey passage virus treated with 1 per cent sterile solution of sodium ricinoleate.[2] This concentration of sodium ricinoleate, however, being very low in bacteriostatic and bactericidal activity, did not prevent the accidental contamination with *B. coli* and a staphylococcus of 3 lots of vaccine prepared in the Research Institute of Cutaneous Medicine, so that the method of preparation was later changed to include 1:80,000 phenyl-mercuri-nitrate. This was found sufficient for protection against contamination during the preparation and administration of the vaccine without producing any material reduction in its immunizing properties.[3]

Since I believe that the method of preparation bears an important relation to the safety of the vaccine for both monkeys and human beings, it may be well to state that it is prepared of spinal cords from paralyzed monkeys following intracerebral inoculation with a remote passage virus. The cords are first kept in 50 per cent glycerol for at least a week, and then *very finely divided* in order to permit thorough mixture of the virus with the sodium ricinoleate and phenyl-mercuri-nitrate at 37° C. for 24 hours, followed by 10 to 14 days in a refrigerator at 10° to 12° C., with daily shaking, when cultural and mouse inoculation tests for sterility are conducted. The brain and cord of each monkey are tested in the meantime for the virus of lymphocytic chorio-meningitis (Armstrong) by intracerebral inoculation of mice which has not been encountered in a single animal.

ATTENUATION OF VIRUS AND OTHER FACTORS OF SAFETY

I believe that the virus in vaccines prepared in this manner has undergone some reduction in virulence or infectivity, which I first designated as devitalization and later as attenuation, but still retains some active virus. As a rule, the intracerebral inoculation of young monkeys with 0.3 c.c. of vaccine has produced some paralysis within 3 weeks and usually within 12 days, but not infrequently this appears more slowly and less severely than when monkeys of approximately the same weight and age are inoculated intracerebrally with 0.3 c.c. of a 4 per cent suspension of fresh untreated virus. The age and weight of *Macacus rhesus* monkeys have been found to have an important influence upon susceptibility,

* Read at the Fourth Annual Meeting of the Southern Branch, American Public Health Association, in St. Louis, Mo., November 19, 1935.

but it has been very difficult to gauge the degree of attenuation of virus by this means.

However, and more important, none of a series of 42 monkeys receiving the vaccine in doses as large as 0.5 c.c. per kg. (corresponding to as much as 5 c.c. for a child of approximately 25 lb.) every 5 days in 5 subcutaneous injections has developed any evidences of poliomyelitic infection, whereas in a control series of 20 monkeys receiving 5 similar doses of fresh untreated virus paralysis developed in 1. Under the circumstances I believe that the manner of preparing the vaccine has resulted in some reduction of infectivity of the virus. This is not due to a mere dilution of the virus, as the amount administered has been the same; but it may be a quantitative change in the sense that the method of preparing the vaccine may result in the inactivation of some of the virus. Nor can it be stated that the reduction in virulence of the virus by treatment with sodium ricinoleate and phenyl-mercuri-nitrate is permanent, as the virus recovered from the cords of monkeys paralyzed by intracerebral injections of the vaccine has usually been found apparently as virulent as untreated virus.

Therefore I think it is better to speak of the effects of sodium ricinoleate and phenyl-mercuri-nitrate upon the virus as being one of slight devitalization or attenuation, although I believe it is a reasonable assumption that some mutation of the virus for human beings may have resulted from the very large number of times in which it has been passed through monkeys. This, of course, has not been proved as it would require the subcutaneous injection of susceptible human beings with fresh unchanged virus, but the probability and possibility exist. Furthermore, while it is possible to produce paralysis of monkeys by intracerebral inoculation with human spinal cord virus, yet this is by no means easily accomplished, indicating that human virus usually requires some adaptation to the monkey before uniformly successful infection can be accomplished. It would appear that Dr. William H. Park shares this opinion, judging from his recent statement[4]:

> It is also known that it is difficult to adapt the human virus of infantile paralysis to monkeys so that they will develop an attack. The reverse of this is probably true: that a virus adapted to infect monkeys has lost much of its virulence for man.

Furthermore, it appears that the subcutaneous route of administration of the vaccine is an additional factor of safety. As stated, none of 42 monkeys receiving the vaccine by this route in relatively large doses has developed evidences of infection, and only 1 in a series of 20 receiving fresh untreated virus, even though the latter has been well adapted to this animal, nor have I been successful in infecting monkeys with human virus by this route although I hasten to add that it has been attempted with the virus from but 5 human spinal cords. I may state that the results of unpublished experiments indicate that it is even more difficult to infect monkeys with intracutaneous injections of passage virus; but I believe the results with subcutaneous injections justify the assumption that this route of administration is not favorable to infection. This opinion is also apparently shared by Dr. Park who has recently stated[4]:

> It is known that when intradermal or subcutaneous methods of injection are used, it is difficult to infect monkeys. There is every reason to believe that this is true of children.

Additional factors of safety in the subcutaneous or intracutaneous administration of the vaccine may be our custom of giving 3 small doses and the rapidity with which neutralizing antibody is apparently produced in some

children[5] and immunity in some monkeys.[6] I am perfectly aware that the amounts of vaccine advised for the immunization of human beings are less than found necessary for monkeys, but I have thought it likely that children will require much less immunization for protection against chance natural infection from contact with carriers or cases of infantile paralysis than is required for the protection of monkeys inoculated by the intracerebral injection of 10 or more minimal infective doses of virus.

It is for these reasons that I have regarded the vaccine as safe for the immunization of human beings when prepared exactly as described.[3] Certainly we have had no success in the immunization of monkeys with vaccines of virus "killed" or inactivated by heat, chloroform, phenol, or formalin. For this reason I believe that effective vaccination requires the presence of some active virus in the vaccine, and in this connection may state that on one occasion we found our vaccine ineffective in the immunization of monkeys when devitalization of the virus was carried out to the point where the intracerebral inoculation of 5 monkeys with 0.3 c.c. produced only mild paralysis of one arm of one of the animals. Why the presence of active virus is apparently required is discussed elsewhere in more detail,[1] but I may mention here that effective immunization in virus diseases may require the prolonged or persistent sojourn of the viruses in the hosts as stated by Rivers,[7] and if this is true of poliomyelitis, it is not unlikely that completely inactivated vaccines cannot produce effective and durable immunity in this disease.

DISTRIBUTION AND ADMINISTRATION OF THE VACCINE

Following our initial immunization of 2 adults and a group of 25 children varying in age from 8 months to 15 years, with absolutely no ill effects,[5] we have during the past 9 months administered the usual 3 doses to 446 additional individuals in Philadelphia,* 319 of whom were children from 6 months to 15 years of age, with no ill effects aside from some local reactions. In this connection I may state that the number of reported cases of poliomyelitis in Philadelphia during this period has been but slightly above the normal rate, which fact I mention because the low rate greatly reduced the chances of giving the vaccine during the incubation period at a time too late to prevent the disease.

Since April the Research Institute of Cutaneous Medicine has distributed 13,112 c.c. of the vaccine to 582 physicians in 36 states, including Canada, mostly in the epidemic areas, and the William S. Merrell Company of Cincinnati have distributed an additional 8,910 c.c. to 137 physicians in the same areas. These amounts, totalling 22,022 c.c. distributed through 719 physicians, have been sufficient for the immunization of over 12,000 individuals (mostly children). Reports have been received up to the present covering the immunization of 8,272 receiving Research Institute vaccine, and 2,007 receiving the Merrell vaccine, a total of 10,725 individuals, including the Philadelphia group, receiving the vaccine divided according to age as follows:

Under 4 years of age,	3,307 or	30.8%
4 to 15 years of age,	6,425 or	60.0%
Over 15 years of age,	993 or	9.2%

REACTIONS

With sterile vaccine, and especially that prepared with the addition of 1:80,000 phenyl-mercuri-nitrate, about 91 per cent had no local reactions aside

* I am indebted to Dr. George F. Klugh, Jr., and Dr. Robert Glenn for assistance in the immunization of these individuals in the clinic established at Temple University Hospital, January 26, 1935.

from slight stinging pain immediately after injection, followed by very slight tenderness for a day or two. In about 9 per cent the local reactions have been comparable to those produced by injections of diphtheria toxoid. Older children and adults have had more reactions than young children. Among the children receiving the 3 contaminated lots of vaccine from the Research Institute of Cutaneous Medicine, abscesses with constitutional symptoms developed in 26, who promptly recovered after drainage. There have been no severe local or constitutional reactions and no abscesses following the injection of vaccine carrying the 1:80,000 dilution of phenyl-mercurinitrate.

Constitutional reactions of slight fever, malaise, headache, some muscle stiffness, and anorexia with slight leukocytosis, subsiding in 24 to 48 hours, occurred in approximately 1 to 2 per cent of those inoculated with sterile vaccine. While skin tests on a small group of normal adults and children[8] have shown no evidences of a natural allergic sensitization to monkey spinal cord protein, there has been 1 case of allergic asthma reported to me following the administration of the vaccine, and a second patient in our clinic developed a mild urticaria following its administration. There have been no instances of demyelinization encephalomeningitis, such as have been reported in connection with the administration of rabies vaccine and regarded by some investigators as due to acquired allergic sensitization to spinal cord substance.

No instances of lymphocytic choriomeningitis have been reported to me following the administration of the vaccine, and we have not yet encountered the virus in the brains or spinal cords of our poliomyelitic monkeys by intracerebral inoculation of mice.

Since the vaccine has been given so extensively and with no restrictions whatsoever in the epidemic areas with consequently greatly increased chances of its administration to individuals during the incubation period, I have always expected that there would be at least some cases of poliomyelitis receiving the vaccine too late to prevent the disease. This possibility and probability were particularly impressed upon me by the fact that the great majority of individuals are apparently infected not by contact with actual cases but by carriers in which the duration of the primary incubation is in truth unknown and likely to be quite variable. Among approximately 11,000 immunized individuals, poliomyelitis developed in 10 who had received 1 or 2 doses of vaccine furnished by the Research Institute of Cutaneous Medicine. In at least some of these, it is a reasonable assumption that the vaccine was not responsible for the attacks, and in no instance has poliomyelitis developed after the full 3 doses of vaccine had been given. The essential facts of these 10 cases are as follows:

ABSTRACTS OF 10 CASES DEVELOPING POLIOMYELITIS

Case 1—The first instance reported to me by Dr. F. Kessel, of Los Angeles, was an adult exposed to the disease, who received 0.5 c.c. of the vaccine 4 days before the onset of a mild attack, exhibiting weakness in both legs and arms. It was obvious that this attack could not be ascribed to the vaccine, and this same lot was administered by Dr. Kessel to 82 additional individuals as well as to 310 (mostly children) in the southern states and our clinic, with no instances of poliomyelitis infection.

The next 2 cases occurred in the practice of Dr. Arthur Heyman of Newark, N. J., where a number of cases of poliomyelitis occurred during the past summer.

Case 2—Sally G., age 5¼ years. On July 5 and 11, the vaccine was given subcutaneously in alternate arms with practically no local or general reactions. July 13, very

transient pain in the back of the neck; July 14, some irritability; July 15, fever, frontal headache, neck stiffness, and vomiting; July 17, stiffness of the neck, with positive Kernig and Brudjinski reflexes; a spinal fluid examination showed a pleocytosis of 260 cells per c.mm.; July 19, flaccid paralysis of the left arm followed by improvement.

If the symptoms presented on July 13 were those of poliomyelitis, as appears probable, the attack began 8 days after the first, or 2 days after the second dose of vaccine. Dr. Heyman did not ascribe the attack to the vaccine, and thought that the two injections may have aided in confining the poliomyelitis to the mild and localized paralysis which in his experience was unusual in a case presenting so much constitutional reaction. The parents insisted upon the immunization of another child in this family.

Case 3—Victor P., age 8½ years. August 7, symptoms of an upper respiratory infection with malaise, irritability, etc.; August 10, given a subcutaneous injection of 0.25 c.c. of vaccine in left arm; August 11 to August 16, mild fever with persistence of upper respiratory symptoms; August 18, some tenderness in right deltoid muscle but no paresis or paralysis when examined by Dr. Danzis; August 27, weakness of the right deltoid muscle. No spinal fluid examination.

Dr. Heyman thought it possible that this child may have had the premonitory symptoms of poliomyelitis on August 7 before the vaccine had been given and that indeed its administration may have aided in rendering the attack very mild. He suspected that infection may have taken place in a swimming pool, as another unvaccinated child developed a severe bulbar type of poliomyelitis apparently from the same source at the same time.

Dr. Heyman gave the same lots of vaccine to 30 additional children under 4 years of age, to 42 between 5 and 15 years, and to 1 over 15 years of age with no evidence of poliomyelitis infection. Both lots were also given to 3 children by Dr. M. G. Dubois, to 5 by Dr. J. B. Rothstein, to 8 by Dr. S. B. Rawitz, to 4 by Dr. G. A. Holland, to 5 by Dr. Harry A. Brotman, to 59 by Dr. A. S. Finkelstein, and to 12 by Dr. R. N. Shapiro, all of Newark, N. J. Of 189 individuals, 54 were children under 4 years of age. The same vaccine was also given to 280 additional children in the southern epidemic areas and my clinic in Philadelphia with no ill effects.

Curiously enough, the next 3 cases also occurred in this same area in the practice of Dr. Richard C. Peters of Plainfield, N. J.:

Case 4—David C., age 10 years. August 24 and August 31, subcutaneous injections of vaccine in the left arm; September 3, developed headache with pain in neck and spine with fever, nausea and vomiting; September 4, rigidity of neck and spine with tremor of both arms. A spinal fluid examination showed 450 cells per c.mm. with a slight increase of protein. At this time 20 c.c. of convalescent immune serum were administered. September 5, flaccid paralysis of right arm followed by death on September 6. No autopsy was conducted.

Case 5—Hugh McD., age 5 years. August 4, first dose of vaccine by subcutaneous injection in left arm; August 31, second dose in left arm; September 6, slight fever and vomiting. An examination of the spinal fluid showed 250 cells per c.mm. September 7, paralysis of legs and arms with death September 9. No autopsy was conducted.

Case 6—Esther P., age 22 months. August 24, first dose of vaccine by subcutaneous injection in left arm; September 5, second dose in left arm; September 11, developed fever, headache, and vomiting, with stiffness of the spine. A spinal fluid examination showed the presence of 760 cells per c.mm. with a slight increase of protein. A transfusion of 350 c.c. of blood from a convalescent case was given, followed by 40 c.c. of convalescent immune serum on September 12; September 14, paralysis of left leg and both arms, ending fatally September 16. No autopsy.

Dr. Peters had given the same vaccine to 49 additional children, 29 of whom were under 4 years of age; Dr. L. D. Williams to 50 children, 15 of whom were under 4 years of age; and Dr. F. W. Lathrop, all of the same city,

to 4 children without any ill effects aside from some local reactions. The same lots were also administered to 262 individuals (mostly children) in other epidemic areas, and to 59 children in our clinic with no ill effects aside from some local reactions.

Case 7—A boy 5 years of age in the practice of Dr. M. W. Sinclair, Bluefield, W. Va. August 20, 0.25 c.c. of vaccine by subcutaneous injection in an arm; August 27, 0.5 c.c. of vaccine by subcutaneous injection in an arm; August 30, headache and vomiting; August 31, tenderness of neck and back with rigidity. Spinal fluid examination showed 648 cells per c.mm. with slight increase of globulin. September 1, paralysis of diaphragm and death. No autopsy.

Case 8—A girl 6 years of age in the practice of Dr. Sinclair. August 20, 0.25 c.c. of vaccine by subcutaneous injection in an arm; August 27, 0.7 c.c. of vaccine by subcutaneous injection in an arm. On September 3, she became acutely ill with poliomyelitis, developing paralysis of the left arm September 6, of the right arm September 8, and of the left leg September 9; September 11, she rapidly improved, talked freely, moved both arms and legs, and has since greatly improved.

Dr. Sinclair had 2 cases of poliomyelitis and 21 additional cases with positive spinal fluid changes, which were either abortive types of poliomyelitis or instances of lymphocytic chorio-meningitis, among unvaccinated children. He gave the same vaccine to 14 additional children with absolutely no ill effects other than very mild local reactions. The lot of vaccine used by him was also given to 93 children, 28 of whom were under 4 years of age, by Dr. R. R. Stuart; to 66 children, 19 of whom were under 4 years of age, and 4 adults by Dr. F. N. Andrews; and to 123 children, 23 of whom were under 4 years of age, and 11 adults by Dr. H. R. Connell, all of Bluefield, as well as to 222 additional individuals (mostly children) in other epidemic areas and in our Philadelphia clinic, with no ill effects. In Case 8 the sudden improvement of the child on September 11, followed by very satisfactory recovery, again suggests that the two doses of vaccine may have contributed to recovery possibly by aiding in the production of antibody.

Case 9—Marie De W., age 8 years; Dr. John M. Higgins, Sayre, Pa. September 8, 0.25 c.c. of vaccine by subcutaneous injection in left arm; September 15, 0.5 c.c. in left arm; September 16, nausea with some pain in the neck; September 17, nausea, vomiting and some pain in the neck; September 18, fever, hypersensitiveness and some abdominal discomfort. Reflexes normal. Later evidences of respiratory paralysis with death on September 19. No autopsy.

Three other children of the same family, 5, 9, and 11 years respectively, were also given the same vaccine with temporary systemic reactions but no other ill effects, and 3 additional children, 5 to 13 years of age, and 6 adults were inoculated with vaccine during the same period with no ill effects. Three doses of the same lot were also given at weekly intervals to 446 individuals (mostly children) in other areas, as well as to 62 children in our clinic, with no ill effects. Through the kindness of Dr. S. D. Conklin, of Sayre, I was able to examine the balance of vaccine in the vial employed in Case 9 and found it sterile upon culture. The intracerebral inoculation of a monkey with 0.3 c.c. produced paralysis 14 days later, but a second animal receiving 5 subcutaneous injections of 0.5 c.c. per kg. every 5 days (corresponding to about 10 c.c. per 50 lb. of weight) were without any ill effects whatsoever.

Case 10—Billy P., age 4 years; Dr. Walter Freeman, Washington, D. C. September 6, 0.25 c.c. of vaccine by subcutaneous injection in the left thigh; September 13, 0.5 c.c. of vaccine in the left thigh; September 14, fever, vomiting, restlessness and pain in the back of the neck; September 17, weakness of the extensor muscles of the right leg, loss of patellar and achilles reflexes, slight fever; September 20, improvement; Novem-

ber 8, striking improvement with almost complete recovery.

This child was in Elizabeth City, N. C., from August 31 to September 3, where, I am informed, there were no reported cases of poliomyelitis. Maids in the family were in a locality of the same state where some cases had occurred. The father, Dr. Matthew W. Perry, was in contact with a case on September 4. Dr. Perry had given the vaccine to Mrs. Perry and his two other children at the same time with no ill effects. Dr. Freeman also gave the same vaccine to 8 additional children, 3 of whom were under 4 years of age, and 2 adults, with no ill effects aside from mild local reactions. The same lot of vaccine was also given to 190 additional individuals (mostly children) in other areas, and to 19 in our clinic, with no ill effects aside from some mild local reactions. On November 8, Dr. Perry kindly wrote me that since the vaccine was given in the left thigh with the onset of the paralysis in the right leg only about 8 days after the first dose, both he and Dr. Leake did not believe that the vaccine was responsible.

It is of course difficult to interpret accurately the etiology of these 10 cases of poliomyelitis occurring among over 10,725 immunized individuals, 90.8 per cent of whom were under 15 years of age, since it is impossible to prove definitely or disprove that they were caused by the vaccine. If due to the vaccine, it is difficult to understand why there were not more cases since the particular lots administered had been given to at least 2,544 individuals, the majority of whom were children in the ages of greatest susceptibility. None of the vaccines were prepared of individual monkey spinal cords but were mixtures of four or more.

Furthermore, the duration of the period of incubation of poliomyelitis in human beings cannot be definitely stated, as one never knows when infection is contracted from a carrier or an abortive case of the disease. Indeed one of its greatest mysteries is the frequency with which isolated cases develop without any possible way of knowing or ascertaining the source of infection. It is commonly stated, however, that the period of incubation is from 1 to several weeks. Six of these 10 cases (Nos. 1, 2, 3, 8, 9, and 10) developed poliomyelitis 8 days or less after the first dose of vaccine, while the others (Nos. 4, 5, 6, and 7) did so in from 3 to 6 days after the second. Under the circumstances I believe it is a reasonable assumption that some at least were in the incubation period of the disease when the vaccine was given and especially since 8 occurred in areas where possible infection with the virus was increased.

It may be stated that the vaccine produced these attacks in individuals of unusually low resistance. I know of no way of proving or disproving such an assumption. Excluding the first case, in an adult where the vaccine could not possibly be regarded as the cause, 2 occurred in children 4 years or younger (Nos. 6 and 10), and the remaining 7 in children from 5 to 10 years of age where resistance is usually higher, since a larger percentage of this age group are known to carry neutralizing antibody in the blood.

It might also be assumed that the vaccine is capable of producing a negative phase of temporarily lowered resistance in some individuals, as is believed may follow the administration of any vaccine. I have not been able to elicit any evidence of this in the experimental disease of monkeys, although it may possibly occur in some human beings despite the fact that the doses are small. If such occurred, however, in unusually susceptible children receiving the vaccine during the incubation period of poliomyelitis, it may

readily result in a severer type of the disease, and this may have occurred in Cases 4, 5, 6, 7, and 9. On the other hand, if Case 3 was in the early stage of poliomyelitis when the vaccine was given, there were certainly no evidences of a negative phase having been produced since the attack was so mild.

However, I am now particularly interested in the intracutaneous injection of the vaccine because preliminary results indicate that much smaller doses may give an equally good or even better immunity response than subcutaneous injection, with possibly much less chance of producing periods of temporarily lowered resistance. And in this connection the recently published work of Rivers and Ward[9] upon intracutaneous injections of culture vaccine virus for immunization against smallpox has renewed our interest in the possibilities of the intradermal use of poliomyelitis vaccine.

Furthermore, the intracutaneous injection of the vaccine may greatly reduce the chances of the virus in the vaccine being conducted to the spinal cord by way of the peripheral nerves or lymphatics, although it does not appear from the 10 cases herein reported that this is at all likely to occur from subcutaneous injections. In Cases 3 and 4, for example, the vaccine was injected in the left arms but mild paralysis developed in the right arms; in case 10 the vaccine was given in the left thigh with paralysis developing in the right leg; while in Cases 1, 6, and 8, paralysis also developed in the legs although the vaccine was given in the arms.

I do not wish to be understood as merely seeking reasons for excusing the vaccine as a possible cause of these 10 cases of poliomyelitis occurring among 10,725 and more inoculated persons; but if the vaccine were primarily responsible, I find it difficult to understand why there were not many more cases among the 2,544 inoculated with the same lots and particularly since 30 per cent of the whole, or 3,307, were children under 4 years of age and therefore in the period of greatest susceptibility. Furthermore, it is not without significance that no one receiving the full 3 doses has contracted the disease. Under the circumstances, I do not personally believe that the vaccine was responsible for all of these cases although I think it is possible that its administration to unusually susceptible children during the incubation period may enhance the severity of the disease by the production of a negative phase, and especially during epidemics when the virulence of human virus is probably increased.

IMMUNIZING VALUE

It is of course too early to express a definite opinion of the immunizing value of the vaccine except to mention again that no one receiving the full 3 doses has contracted poliomyelitis. Only the lapse of many years will eventually reveal whether or not any immunized individuals develop the disease. In this connection I very carefully considered the manner of distributing the vaccine for the purpose of securing the best possible check-up and adequate controls, and finally decided that since we were financially unable to establish social service departments for follow-up work, this could be best handled through individual physicians keeping the addresses of immunized persons and using the much larger group of unvaccinated individuals in each community as controls. After all, and in the final analysis, it is essentially a matter for determining whether or not any vaccinated persons, especially children, develop the disease during the present epidemic or in the future, and this demands the immunization of as many as possible with subsequent observations over years, which I finally

decided could be best done through individual physicians.

It is true that additional data of some scientific value may be obtained by conducting monkey serum neutralization tests before and after immunization to determine the number responding with the production of neutralizing antibody. Unfortunately, since our work was financed and made possible only by voluntary contributions from physicians, we were not able to conduct as many of these tests as we had hoped. It would appear, however, that enough may have been conducted to indicate that neutralizing antibody is produced in over 80 per cent of vaccinated individuals, but it remains to be seen whether or not this is adequate for effectual resistance to the disease. I have reason to believe [1] that the antibody produced in human beings by active remote monkey passage virus is capable of neutralizing human virus, and under the circumstances I believe one can reasonably assume and expect that it will afford a state of resistance to infection. Furthermore, since there is apparently in poliomyelitis an important tissue immunity,[1] it is not unlikely that the vaccine may produce a type of immunity not to be measured or ascertained by monkey serum neutralization tests. This is conjectural only, and awaits final elucidation by the passing of years, with follow-up observations on a very large group of vaccinated individuals and particularly young children.

I am confident that the vaccine prepared exactly as described so as to contain at least some active virus is capable of immunizing monkeys and the production of the immune state in these animals was always determined by injecting them intracerebrally with 5 or more minimal infective doses of virus. Unfortunately we were unable to finance neutralization tests with the sera of these monkeys before and after immunization, so that I am unable to discuss the relation or lack of relation of neutralizing antibody to resistance in these animals; but, after all, the results of intracerebral tests would appear to be the better criterion when controlled by the intracerebral inoculation of an adequate number of unvaccinated animals, as we were fortunately able to do.

From the fact that the vaccine is capable of successfully and effectively immunizing monkeys, and since it has produced neutralizing antibody in children capable of neutralizing human virus in about the third monkey transfer, I am reasonably confident that the vaccine is capable of effectively immunizing human beings against the disease.

It is, however, still too early to express an opinion on the probable duration of this induced immunity except to state that 3 monkeys have maintained a solid immunity for 3 years. I have now discarded the animals, because their age may alone account for at least a part of this resistant state to intracerebral inoculations with virus, and for this reason further tests would appear to have but little scientific value. It is not without significance and encouragement, however, that monkey neutralization tests with the sera of 23 out of the original group of 25 children [5] immunized 11 months previously, have shown the persistence of antibody in all who showed its presence when tested 1 week after the third dose. Indeed, one child without demonstrable amounts of antibody in tests conducted at that time showed its presence in these repeat tests conducted this year. I believe therefore that the immunity produced by the vaccine is an enduring one, and if it lasts only a sufficient number of years to protect children over their age of greatest

susceptibility until the natural immunity of maturity has been reached, it seems well worth while.

SUMMARY

1. It would appear that effective vaccination against acute anterior poliomyelitis requires the administration of active virus.

2. Treatment of remote monkey passage virus with sodium ricinoleate and phenylmercuri-nitrate by the method described has resulted in sufficient attenuation to render the vaccine safe for the vaccination of monkeys.

3. The injection of such vaccine subcutaneously also appears to be an important additional factor of safety.

4. It is suggested that the remote monkey passage virus employed in the preparation of the vaccine may have lost some infectivity for human beings by the subcutaneous route of administration.

5. The amounts of vaccine employed for the immunization of human beings has been less per body weight than used for the immunization of monkeys because it is believed that less immunity will be required for adequate protection against natural infection with human virus.

6. The vaccine has been employed in the immunization of 10,725 individuals mostly in epidemic areas. Of these 3,307 (30.8 per cent) were under 4 years of age; 6,425 (60 per cent) between 5 and 15 years; and 993 (9.2 per cent) over 15 years.

7. With sterile vaccine local reactions at the sites of inoculation occurred in about 9 per cent with constitutional reactions in from 1 to 2 per cent.

8. There is no evidence of the vaccine having produced lymphocytic chorio-meningitis or demyelinization encephalo-meningitis.

9. No individual who received the full 3 doses has developed poliomyelitis. Among the 10,725 inoculated individuals there were 10 cases of poliomyelitis following 1 or 2 doses. Two were 4 years old or younger; 7 were between 5 and 10 years; and 1 was an adult. The same lots administered to these individuals were given to 2,544 additional persons (mostly children) without ill effects. An analysis of these cases indicates that some were probably in the incubation period of the disease when the vaccine produced a temporary period of lowered resistance or a " negative phase."

10. It is believed that the vaccine is probably safe for the immunization of human beings and especially when given during non-epidemic periods.

11. It is too early to express an opinion of the practical immunizing value of the vaccine, as a large group of vaccinated children must first be observed over a period of years. The results of immunization of monkeys and serum neutralization tests of children for antibody indicate, however, that effective immunization is possible.

12. The duration of the immunity cannot be given at present except to state that it has endured in monkeys up to at least 3 years, and antibody has persisted in children for at least 11 months. If, however, the immunity is found to protect children over their age of greatest susceptibility, it would appear that vaccination may be well worth while.

Immunity in Virus Diseases With Particular Reference to Poliomyelitis*

THOMAS M. RIVERS, M.D.

Hospital of The Rockefeller Institute for Medical Research, New York, N. Y.

INFECTIOUS diseases are caused by protozoa, fungi, spirochetes, bacteria, Rickettsia, and viruses. At this time, however, we shall limit our remarks to certain phenomena associated with the diseases caused by the viruses or filterable viruses.

It is very difficult to define the term viruses. Nevertheless, the word has a very definite meaning to those actively working with them. Probably the best way to convey to you what is meant by these active agents is to enumerate some of the diseases incited by them, for example, bacteriophagy, mosaic diseases of plants, polyhedral diseases of insects, certain filterable tumors of fowls and rabbits, fowl-pox, fowl plague, foot-and-mouth disease of cattle, equine encephalomyelitis, psittacosis, rabies, measles, smallpox, vaccinia, varicella, fever blisters, St. Louis type of encephalitis, warts, poliomyelitis, yellow fever, etc.

From what has been said it is obvious that viruses cause a large number of devastating maladies. These incitants of disease are much smaller than ordinary bacteria, are invisible in the unstained state by means of ordinary light, and are obligate parasites in the sense that they have not been cultivated in the absence of living susceptible host cells. Their exact nature has not been determined. In fact, the viruses were first shown to exist and are still principally recognized clinically and experimentally by means of their activity in a host.

As public health officers and physicians, you are undoubtedly interested in measures directed toward the control, prevention, or eradication of the diseases caused by viruses. Quarantine measures are of little or no value in controlling measles, poliomyelitis, encephalitis, varicella, etc. The most successful known method for controlling certain virus maladies is by vaccines prepared and administered in the proper manner—for example, vaccination against smallpox, yellow fever, rabies, canine distemper, etc. In order to appreciate the difficulties encountered in developing an efficacious vaccine against a virus disease, one must have some understanding of the immunological phenomena observed in the virus field. It is with some of these phenomena that I shall deal before specifically discussing prophylaxis against poliomyelitis.

It has been shown that agglutinins, precipitins, complement-fixing antibodies, and neutralizing or protective antibodies may appear in the sera of

* Read at the Fourth Annual Meeting of the Southern Branch, American Public Health Association, in St. Louis, Mo., November 19, 1935.

individuals who have recovered from certain virus diseases. Moreover, an obvious infection with a virus usually leads to a state of increased resistance in the recovered host to further molestation by the same agent. It is of no particular interest, however, that such things take place in virus diseases, because they are known to occur in other types of infection. Nevertheless, there are some facts of particular interest which deserve consideration at this time:

1. Why is it so difficult to obtain an efficient immunity against virus infections by means of injections of vaccines composed of inactivated viruses?
2. Are the agglutinins, precipitins, complement-fixing antibodies, and protective antibodies the result of the stimulation of a host by means of a single antigen?
3. In what manner do the neutralizing or protecting antibodies act?
4. Why do so many virus diseases lead to a permanent immunity in recovered hosts?

Questions arising in regard to the immunization of individuals with inactive viruses are difficult to answer, because it is almost impossible at present to determine when a virus has been completely inactivated. For example, Lippert doubts whether Perdrau and Todd, by means of methylene blue and light, completely inactivated the canine distemper virus which later was shown to immunize dogs against distemper. Furthermore, Dunkin and Laidlaw have shown that formolized canine distemper virus will produce a fleeting immunity in vaccinated dogs, but in order to get a solid lasting resistance active virus must be employed. In the literature, statements are found that inactive viruses can act as efficacious vaccines, and canine distemper and yellow fever are cited as examples of diseases that can be prevented in this manner. Such statements are incorrect because field experiments with these two diseases offer no evidence that vaccines of inactive virus will prevent epidemics of them.

Certain workers are of the opinion that the amount of inactive virus is the all important factor, *i.e.*, if a sufficient amount were used, a solid immunity would result. Mackenzie reported that with small doses of inactive Rift Valley fever virus he was unable to immunize mice, while with large doses, 1 c.c. administered intraperitoneally, he was able to establish a good resistance in the animals to the active agent. Assuming that the virus was completely inactivated and that the mice were solidly protected, one must remember that a mouse weighs in the neighborhood of 20 gm. and that 1 c.c. or 1 gm. of the virus emulsion was administered, *i.e.*, approximately 1/20 of the body weight. On the basis of these figures a man weighing 150 lb. would require 7½ lb. of vaccine—not a very practical procedure.

When one brings up the question of the production of immunity by an inactive virus, antirabic vaccination is cited as an example of protection induced in this manner. I am glad to find, however, that some workers are no longer willing to accept dogmatic statements handed down to them in regard to antirabic vaccination, but insist upon exploring the field for themselves. As a result of this healthy skepticism it is being found that many batches of the Semple phenol-killed antirabic vaccine on the market will not immunize animals even when repeated large doses are employed. Nor is it surprising to find that the practice of giving dogs one dose of this material is frequently attended by the failure of the animals to be protected against rabies subsequently acquired through the bites of rabid animals.

Whatever viruses may be, in the active state they are antigens, and as such one would like to think of them

as containing proteins, or at least as being linked in some way to proteins. Therefore, if sufficient amounts of these agents in an inactive state, yet with their antigenic components not altered by inactivation, were administered to subjects in the form of vaccines, I would not be surprised to find complement-fixing antibodies, etc., appearing in the sera of vaccinated individuals; nor would I be disturbed to find that a certain amount of resistance to infection had resulted. In the past, however, it has not been possible to obtain viruses in sufficient amounts in a relatively pure state to determine what happens to their antigenic components when inactivated. Recently, Craigie has opened up this field in regard to vaccinia and has found that vaccine virus is composed of several antigens some of which are extremely labile and appear to function in the production of resistance, while others are stable and induce the formation of agglutinins, etc. Parker, working in my laboratory, has confirmed many of Craigie's findings. What Craigie has accomplished for vaccinia must be done with other virus maladies, and, in the meantime, generalizations should be suspended.

For the sake of argument let us assume that it has been demonstrated that a certain degree of immunity can be obtained by a completely inactive virus provided sufficient amounts are administered. What about the duration of the protection induced in this manner? All the evidence at hand seems to indicate that whatever protection is produced in this way endures only for a relatively short time. Even this fact is admitted in regard to the antirabic vaccination of dogs, the yearly repetition of which is advised. Furthermore, the Pasteur treatment is repeated each time a human being is bitten by a rabid animal. Strange to say, many workers do not seem to be disturbed by this fact. In the case of hogs and cattle that are raised for the meat market and will live for a short time only it is not necessary to produce a lasting immunity. Nevertheless, the duration of an immunity produced by vaccines, particularly when the vaccines are expensive to make and difficult to administer, is of great importance in the protection of human beings against smallpox, yellow fever, measles, poliomyelitis, etc.

As a rule, the serum from a host recovered from a virus disease possesses neutralizing or protective properties. For instance, an appropriate amount of convalescent serum mixed with the homologous virus results in what is called a neutral mixture, *i.e.*, the mixture of virus and convalescent serum does not produce evidences of disease in a susceptible host. Furthermore, in many instances, sufficient convalescent serum injected into a susceptible host prevents the production of disease by the homologous virus inoculated just prior to or within a short time after the administration of the serum. The latter fact is the basis for the use of convalescent or immune serum in the prophylaxis against virus maladies, including poliomyelitis. However, the results with poliomyelitis are not as striking as are those obtained with measles, and the passive protection thus developed in monkeys against poliomyelitis endures only for a few days.

The manner in which the neutralizing or protective antibodies act is not known. In spite of this fact, most workers are agreed that the viruses in the so-called neutral mixtures which are usually injected into animals shortly after preparation are not really dead or inactive.

Viruses seem to multiply inside of cells, and it has been repeatedly shown that, once the viruses have come in contact with susceptible cells or have entered them, the protective or neu-

tralizing properties of convalescent or immune serum have no power of preventing injury or death of the parasitized cells. Furthermore, it has been shown that cells may be infected several days before any evidences of such infection are obvious. Usually, by the time an infected host begins to show signs and symptoms of a virus illness, all the cells that are going to be involved during that attack have already been entered by the infecting agent. Consequently, in virus maladies serum therapy given after the onset of signs and symptoms of illness is of little or no value. There is ample experimental and clinical evidence that such is the case, and poliomyelitis seems to be no exception to the rule.

It is a well recognized fact that recovery from a virus infection is usually followed by an enduring immunity. In many instances the immunity is operative during the remainder of an individual's life. Of course there are exceptions to the rule. For example, common colds recur repeatedly in the same individual, and herpes simplex or fever blisters occur at frequent intervals in the same subjects. The persistence of immunity in hosts recovered from virus diseases is so striking that it is not surprising that an explanation of the phenomenon has been sought. Furthermore, if it is the rule to encounter a lasting immunity in virus diseases, one would like to know the reason for the exceptions.

In the case of poliomyelitis and measles, the viruses of which one encounters from time to time throughout life, one might explain the persistent immunity and the presence of neutralizing antibodies on the basis of repeated contacts with the active agents. On the other hand, it is impossible to explain in such a manner the enduring immunity to yellow fever, which is accompanied by the presence of humoral antibodies, in individuals who have been out of yellow fever zones for periods of 25 to 50 years.

In view of the facts mentioned above, and because it is known that a refractory state to some bacterial and spirochetal diseases is associated with a persistence of these agents in the hosts, it has been suggested by a number of workers that at least in certain instances the protracted immunity following virus diseases is due to a prolonged or a persistent sojourn of the viruses in hosts once infected. This persistence of the viruses does not indicate that the hosts are capable of spreading disease.

Without enumerating them, I can state that sufficient instances in which viruses have been recovered from immune hosts have been recorded to show that it is not an unusual occurrence. Nor is it unlikely that, in certain instances, there is a causal relation between the persistence of the virus and the enduring immunity of the host. Moreover, it must be remembered that failure to recover a virus from an immune host is not necessarily positive evidence that it is not present.

In what way is it possible for viruses to persist in an immune host? It is most likely that these agents are intracellular parasites, and as long as they remain situated within living cells are in no danger of being eliminated from the body. If they do not kill the host cells, they can multiply and pass into daughter host cells. In this manner it is possible for them to remain indefinitely in an immune host. Such is undoubtedly what happens in the case of the Rous tumor.

At this point it is well to speak of the apparent lack of a lasting immunity to fever blisters. This disease is particularly interesting because the individuals who have recurring attacks possess an abundance of neutralizing antibodies in their sera. The paradox has been explained on the basis of the

persistence of the virus in the cells of immune individuals, who develop crops of blisters whenever subjected to the conditions that are encountered as the result of typhoid vaccination, common colds, and exposures to high temperatures for several hours, etc.

Why does one fail to develop a permanent immunity to common colds? I do not know. It is interesting to speculate, however. The cold virus may be unable to establish itself permanently in the host; it may act in a manner similar to that of fever blister virus; or the superficial nature of the infection caused by it may have something to do with the poor development of immunity.

Experience showed that recovery from most virus diseases results in an enduring immunity. Later it was found that the sera of individuals recovered from certain of these maladies possess neutralizing or protective antibodies. Consequently, a number of workers think that the presence of neutralizing antibodies in the serum of a person always indicates that the individual is immune. This is probably true when the antibodies are the result of a natural infection. In other words, the individual is known to be immune not because of the antibodies, but because of recovery from a natural infection as indicated by the presence of antibodies.

The state of affairs may be different when a host is artificially immunized against certain virus maladies. Why? —I do not know. In any event, in vaccinated individuals resistance to infection does not necessarily parallel the presence of neutralizing antibodies, as has been demonstrated in dogs vaccinated against rabies. That is, vaccinated dogs may possess neutralizing antibodies and still be susceptible to rabic virus. Parker and I have found a similar state of affairs in rabbits that had received repeated injections of formolized elementary bodies of vaccinia; some of the animals had neutralizing antibodies for vaccine virus without being resistant to a vaccinal infection. Furthermore, Hudson, Schultz, and Olitsky have shown that monkeys vaccinated against poliomyelitis may be susceptible to infection in spite of the presence of neutralizing antibodies in their sera. It is evident that the above observations are of significance when one attempts to evaluate the work of Brodie and Kolmer who lay a great deal of stress upon the fact that monkeys and human beings vaccinated according to their methods against poliomyelitis develop or increase the amount of antibodies in their sera.

In the light of the general remarks regarding the immunological phenomena observed in the virus field, the following specific statements about poliomyelitis and the vaccines prepared by Brodie and Kolmer will be more intelligible.

There is one fact that must be held in mind. It is that the virus of poliomyelitis, either active or inactive, acts as though it was a poor antigen. Even large amounts of it in the active state administered intracutaneously or subcutaneously do not regularly produce resistance to infection in monkeys. Furthermore, intracerebral doses of active poliomyelitis virus, too small to induce an obvious infection in monkeys, will not immunize the animals. Thus it does not follow that the introduction of active virus into monkeys and human beings will result in their effective immunization against infection. This fact is well illustrated by the findings of Schultz and Olitsky who repeated Kolmer's work on monkeys and were unable to demonstrate as much protection as that reported by Kolmer for his animals.

The amount of antigen in the form of active poliomyelitis virus is a very important item in attempts to immunize monkeys by way of the intracutaneous

or subcutaneous route. Even large amounts are not always effective, and investigators working in the effective range have invariably found that an occasional monkey becomes paralyzed as a result of the immunizing doses, and, for this reason, have considered it inadvisable to use active virus for the vaccination of human beings.

In view of what has just been said, the fact that there is, so far as I know, no comparable number of unvaccinated children, properly chosen in regard to location and age, to act as controls for the efficacy of the vaccine in the individuals receiving it, leaves us with a lack of definite information regarding the value of Kolmer's vaccine in the prevention of poliomyelitis in human beings.

Kolmer bases his claim for the safety of his vaccine upon the fact that it is prepared from remote monkey passage poliomyelitis virus that has been further attenuated by contact with glycerol, sodium ricinoleate, and phenylmercuric-nitrate. A statement that monkey passage poliomyelitis virus is less infectious for man than is the natural or human virus is an assumption without experimental evidence to substantiate it. Investigators familiar with work in the virus field would not put too much dependence on such an assumption. It is true that the passage of some viruses through unnatural hosts decreases their virulence for the natural ones. However, this is by no means a regular occurrence.

Many workers state that single applications of certain chemical agents attenuate viruses. This is true if they mean by such a statement that some of the virus units are completely inactivated while others are uninfluenced. In other words, it is usually a misconception to think of this kind of attenuation of viruses as a decrease in the virulence of each virus unit instead of a decrease in the number of active unaltered ones. The evidence is that when a virus emulsion has been treated with a chemical agent and is still capable of causing disease, even though the incubation period is greatly prolonged, the virus recovered from the sick animal is fully virulent. Thus it appears that attenuation by a single application of chemicals is as a rule equivalent to dilution. Dilution alone is the principle employed in the Högyes and Harris methods of vaccination against rabies. In reality, it is the principle operative in the drying of the cords for the old Pasteur method of vaccination. Consequently, it is unlikely that the virulence of each unit of poliomyelitis virus in Kolmer's vaccine is altered by the chemicals used. Therefore, just as good results probably could be obtained by dilution of the virus emulsions as by treatment of them with chemical agents. In fact, it might be better to use diluted material, because then it would be unnecessary to administer a large quantity of useless but troublesome brain substance.

Kolmer admits that at least 10 cases of paralysis have occurred after 1 or 2 doses of the vaccine, and assumes that they were not caused by its administration but by a natural infection acquired through exposure. In support of this assumption, he considers to be of significance the fact that paralyses have occurred after the first or second dose of vaccine instead of the third. Many workers would agree with him that the fact is significant, but would not agree with him in regard to his interpretation of the significance.

It must be remembered that the vast majority of children vaccinated would never have contracted poliomyelitis even though they had not received the vaccine. For unknown reasons, most children are much more resistant to poliomyelitis than are the remaining few. It is possible that the resistant

children were able to stand 3 doses of vaccine, while the most susceptible, the ones highly in need of protection, could not resist the active virus in the vaccine and same down promptly with poliomyelitis after 1 or 2 doses. I do not contend that this is the correct interpretation of the state of affairs, but it is just as plausible, if not more so, than the one offered by Kolmer, *viz.*, that the children were paralyzed by virus acquired through natural exposure instead of by the active virus in the vaccine. Therefore, in view of certain pertinent facts regarding the cases of paralysis following his vaccine it is essential for Kolmer to show definitely that it is safe.

Brodie has chosen to use what he says is inactive poliomyelitis virus for the vaccination of monkeys and children. Others employed such a virus for the immunization of monkeys many years before Brodie, and found the results so discouraging that the matter was not pursued in man.

All of Brodie's favorable results depend on his ability to titrate regularly and accurately 1 minimum completely paralyzing dose of virus. If this cannot be done, then all of his reported findings are invalid. So far as I know, no one has been able to obtain titration results similar to Brodie's, and this is not due to a lack of efforts to do so. Furthermore, Schultz and Olitsky have attempted to immunize monkeys with a vaccine prepared according to Brodie's method and have been able to find little, if any, protection in them against infection.

Recently, I had the opportunity of discussing the matter with Brodie and came to the conclusion that no case of poliomyelitis can as yet be ascribed to the use of his vaccine. Nor could I find any evidence for or against the efficacy of his vaccine. If I were asked for a prophecy, I would say: If Brodie does not make the time of inactivation of the virus too short, and if he continues to administer the vaccine in the manner now employed, it will be reasonably safe but ineffective, particularly if one expects an appreciable degree of protection to persist for any great length of time.

I trust that I have not burdened or bored you with details of immunological phenomena in the virus field. My remarks were made with the intention of showing that there is no reason at present to believe that the general principles of immunity, many of which are not known or understood, fail to operate in this field, and that most of the immunological and serological oddities encountered in this domain can be accounted for by the intimate type of parasitism exhibited by the viruses or by the multiplicity and lability of antigens involved. Finally, it was necessary to present many of the details in order to emphasize sufficiently the fact that it may be difficult, but I hope not impossible, to devise satisfactory vaccines for the prevention of certain virus maladies.

DISCUSSION OF POLIOMYELITIS PAPERS

HENRY F. VAUGHAN, DR.P.H., F.A.P.H.A.
Commissioner of Health, Detroit, Mich.

FROM the viewpoint of the public health administrator I assure you that it it is very essential that we have some definite advice as to what procedures we should follow in our endeavor to control poliomyelitis, and we would like to know whether we have reached the stage where there is a vaccine which is reasonably effective and at the same time safe.

Dr. Kolmer brought out the fact that there had been reported several cases of illness suggestive of poliomyelitis following the administration of 1 or 2 doses of his vaccine but in no case had clinical poliomyelitis been reported in a child who had received 3 full doses of the vaccine. He reports 10 cases which have been officially diagnosed as poliomyelitis following the use of the vaccine, 5 of which died, and also he states that 8 of these cases occurred in localities where poliomyelitis was epidemic, and among these he included the cases in New Jersey.

The official records of the Newark Health Department indicate that prior to September 20, 1935, there had been reported 21 cases of poliomyelitis, 1 in June, 1 in July, 5 in August, and 14 in September. The June case died as did 2 of the September cases. This incidence of poliomyelitis prior to September 20 is approximately the normal expectancy for 1935 based upon previous experience in this community.

In Dr. Kolmer's report he cites 1 case having occurred in July in Newark following the administration of the vaccine and as but 1 was officially reported to the health department, I am led to the inevitable conclusion that this is the case to which Dr. Kolmer referred. It would not appear that poliomyelitis was epidemic in Newark at the time the case occurred.

There were also reported in Dr. Kolmer's series 2 cases which developed following the administration of vaccine in Plainfield, N. J. One child received his initial dose of vaccine on August 24, his second dose on August 31, was taken ill on September 4, admitted to the hospital on the 5th, and died the following day. The second child received his first dose of vaccine early in August, his second August 31, and developed symptoms of poliomyelitis on September 6, was hospitalized and died on September 9. These are the official records which I have obtained from the Health Department at Plainfield. I have also been informed that during the first 19 days of September there were but 5 cases and 2 deaths from poliomyelitis officially reported to the Health Department of Plainfield, and I would assume that the 2 cases to which Dr. Kolmer referred, both of which terminated in death, must have been included in the series. Again, it would not appear that poliomyelitis was epidemic in this community at that time.

Dr. Kolmer further stated that he had included in his series all instances where children had contracted a disease suspicious of poliomyelitis following the giving of his vaccine, but I fail to find any reference to a case which was officially reported in Detroit in the month of August. It is true that this Detroit case has been explained

by the attending physician on the basis of previous exposure, but if Dr. Kolmer is to include in his series all cases which are to be explained on this basis, he should, I believe, include the Detroit case.

The official records in the possession of the Detroit Health Department indicate that a 10 year old boy was seen by a local physician on August 10, complaining of fever, headache, and a sore neck of 3 days' duration. This case was diagnosed as tonsillitis. The child, however, had been attending a boys' camp and one of his tent-mates had been reported as having poliomyelitis. Accordingly, the attending physician administered the first dose of Dr. Kolmer's vaccine on August 10, and our records indicate that the second dose was administered on August 17, and the child admitted to the Herman Kiefer Hospital on August 21, where he remained for nearly 3 weeks, and where the case was considered as a non-paralytic form of poliomyelitis. The child recovered.

I wish to reëmphasize the fact that from the epidemiologic evidence at hand it does not appear reasonable to explain all cases of poliomyelitis following vaccine as due to previous exposure. I would wish to have far more detailed information concerning the life case history of each. Also, I do not personally believe that the public health administrator is justified in using this vaccine as a part of his poliomyelitis control procedure; in fact, with the evidence at hand, it would be most inadvisable for the health officer to use this vaccine.

C. H. HALLIDAY, M.D.

Epidemiologist, Maryland State Department of Health, Baltimore, Md.

I AM thoroughly convinced that there are several types of this disease and that mild or variant forms exist in which there is no detectable evidence of meningitis or myelitic involvement, and that there is very little uniformity of opinion with regard to their diagnostic criteria. The perfectly frank cases may be considered those cases which develop paralysis in association with the usual signs of the disease. My own concept of the disease has been drawn from the observations of 1,274 cases in one epidemic and several lesser epidemics. Of the 1,274 cases, 812 were definitely paralyzed, and in 118 of the 812, the spinal fluid showed a varying degree of cellular increase ranging from 8 to 8,000. Two hundred and five of the cases were classified as abortive; the limits of the clinical picture of this type is uncertain, but in my observations it consisted of an acute febrile disease, the temperature lasting from 12 to 72 hours, vomiting, sore throat, pain and tenderness, slight stiffness of the neck or back, and the patient left feeling below par for several days. In this group the statement was frequently made by the mother that all the children in the family had been ill and one eventually developed paralysis. Two hundred fifty-seven of the cases were classified as "type unknown," falling into the class suggested by Frost: "those in which the clinical symptoms were so indefinite as to furnish no basis for a differentiation from various common infections, but on account of intimate association with a definite case, the diagnosis was suggestive."

I believe the abortive type to be very

common, manifested especially during epidemics by such minor symptoms as fever, headache, and vomiting. It is this type which is frequently referred to as "summer influenza," "summer grippe," acute tonsillitis or gastroenteritis. From my limited knowledge of the 1935 epidemic in Virginia, I am inclined to believe that had only frankly paralyzed cases been accepted, the number reported would have been far less.

It appears to me that the disease occurs in different severity in different epidemics, one epidemic showing a majority of paralytic cases and another in the same locality being characterized by the non-paralytic or sub-clinical type. I believe Dr. Leak's observation will bear this out.

In one epidemic where the opportunity existed to make a post-clinical study of abortive cases, it was found that reflexes were diminished or absent and definite muscle weakness established in one or more groups of muscles, and in a few instances where a biopsy was obtained, it was demonstrated by microscopical examination that there actually existed degeneration of muscle fiber in which no gross disturbances of function was demonstrable.

As to vaccines for the prevention of this disease, I believe the scientific research should continue, but their use should be limited to a few selected persons, so that methods may be uniform and results carefully studied.

JOHN F. KESSEL, M.D.

Department of Bacteriology, School of Medicine, University of Southern California and Los Angeles County Hospital Laboratories, Los Angeles, Calif.

THE first papers of this symposium, giving the experience of the workers in the recent epidemic of poliomyelitis in North Carolina and Virginia, have presented material which indicates that we in California are not the only individuals who experience the unusual. It would appear from their reports that the recent epidemic through which they have passed has many parallels, particularly with reference to the spinal fluid picture, the low mortality and low residual paralysis rate with our experience in the epidemic of 1934 and 1935 in Southern California.

We have often had the question raised as to whether we were actually dealing with typical poliomyelitis, and in attempting to answer have proceeded with caution. The experiences recorded today encourage us in the opinion that we were dealing with poliomyelitis in Southern California, though in a somewhat atypical form.

One aspect of special interest in our epidemic was the high communicability rate as illustrated by the large number of doctors, nurses, and other hospital employees who become infected. In 1934 some 200 of our employees developed poliomyelitis, and during the summer of 1935 approximately an additional 50 developed the disease.

The fact that most of those coming down in 1935 were individuals who were not working in the hospital during the 1934 epidemic, and therefore had developed no immunity, brought us face to face with the question as to whether or not in our institution we should use the vaccines being reported as having merit. Our hospital poliomyelitis committee sent representatives

to the Bakersfield area where some 2,000 cases had been vaccinated with the Brodie vaccine with no untoward results. After careful consideration the committee decided that it would be unfair to withhold the vaccine, which might possess merit, in such an emergency, and accordingly made arrangements with Dr. Brodie and Dr. Kolmer, both of whom transmitted definite statements to the hospital authorities declaring their belief in the safety of their products, to give their vaccines to volunteers who would sign a statement recognizing the fact that they were in their experimental stage and thereby assuming responsibility. Minors who took the vaccines were required to have their parents sign the records. In all, 416 received the vaccines, as indicated by Table I:

It will be observed that the Brodie vaccine was given to a greater number than was the Kolmer, the reason being that certain members of the committee considered that a vaccine made from living virus might possess potential dangers, and therefore it was considered safer to discontinue its use, since we preferred to allow groups other than ours to experiment with this type of vaccine.

The table shows the distribution of the vaccinated individuals among the employee groups to which they belonged. It is difficult to keep adequate parallel controls in a series of vaccinated individuals of this type and it has been found impossible to do so with each group individually.

There is one group of nurses, however, which has yielded rather interesting results. This is made up of student nurses and affiliate student nurses who came to work in the Los Angeles County Hospital following the peak of the 1934 epidemic. Altogether, since October 4, 1934, to June 1, 1935, 189 came to work in the hospital. Of these, 45 had developed poliomyelitis by June 15, the date that our vaccinations began, leaving 144 who were well at that time. Of the 144, 70 received vaccine, either Brodie's or Kolmer's, and 74 were not vaccinated. Of the vaccinated, 2 developed poliomyelitis within 3 or 4 days after the administration of the vaccine, 1 from the Brodie series and 1 from the Kolmer series. Of the unvaccinated, 1 developed poliomyelitis within this time. These 3 cases should be ruled out since they undoubtedly were in the incubation stage at the time the experiment began. Of the remainder, none developed poliomyelitis among the vaccinated, while 3 came down during July among the unvaccinated.

The results may be reduced to include only nurses who came to work after February 1, 1935, leaving out from the series those who began to

work in October, 1934. These results may be tabulated as follows:

			Developed Poliomyelitis
Received vaccine	Brodie's	27	None
	Kolmer's	15	
		42	
Received no vaccine		50	3

From these few cases it is seen that 6 per cent of the unvaccinated subsequently developed poliomyelitis, but none of the vaccinated. These data are few in number and I hesitate to attach great significance to them. However, since no untoward results have developed, it would appear, in so far as our records are concerned, that its use is not contraindicated.

Of interest is the type of reaction following vaccination. Local reactions were, as a rule, moderate and no abscesses developed at the site of injection. There were, however, a number of severe constitutional reactions, 9 among those receiving the Brodie vaccine and 5 among those receiving the Kolmer vaccine. In each instance there was a marked soreness at the point of injection and about 4 hours after the injection a generalized reaction with chills and fever developed, which lasted from 6 to 10 hours and then subsided. Soreness was marked in these cases and lasted for 24 hours.

MAURICE BRODIE, M.D., F.A.P.H.A.

Bureau of Laboratories, Department of Health, New York, N. Y.

INASMUCH as the formalized vaccine we have been using appears to be perfectly safe and inasmuch as there is nothing to contraindicate its efficiency, we feel that further controlled studies should be continued until a definite evaluation can be obtained. This can be accomplished only through a strictly controlled distribution of the virus through health officers or clinics with the proper follow up.

It is agreed by all that heat killed vaccine cannot produce immunity, but there is evidence that viruses rendered non-infective by other means may still be antigenic. Examples have been cited, and Dr. Rivers has mentioned the action of methylene blue and light on various viruses. Studies such as these indicate that the changes may be either quantitative or qualitative. For example, we have found Semple vaccine non-infective for guinea pigs and rabbits, yet it may infect the more susceptible mouse. This, and the fact that formalin treated vaccine gives an antibody response only when the formalin acts for the shortest time required to render it non-infective, suggests the possible presence of an amount of virus too small to infect. An example of a qualitative change is the action of methylene blue and light in which a virus becomes non-infective and antigenic.

One cannot always interpret human experiments in the light of results of animal experiments and so a method that produces a small degree of immunity in the monkey, which is a difficult animal to immunize, may be far more efficacious in the human. This has been suggested by the better antibody response of children to the vaccine. Moreover, no immunity is absolute and a moderate degree in children may be built up more strongly and maintained through further exposures.

DISCUSSION (*Cont.*)

JAMES P. LEAKE, M.D.
Senior Surgeon, U. S. Public Health Service, Washington, D. C.

IT was not my intention to participate in this discussion, but since my name has been mentioned, I must state that I did not express a belief that the vaccine was not responsible for Case 10. In any individual case the possibility should be left open that natural infection was operative, but the meaning of the series as a whole is clear to me, and I beg you (Dr. Kolmer) to desist from the human use of this vaccine. According to my count of the onsets, 1 fatal case occurred 6 days after the second dose, another fatal case 6 days after the second dose, and 12 days after the first dose, 2 paralytic cases and 1 fatal case 8 days after the first dose, a fatal case 9 days after the first dose, another fatal case 10 days after the first dose, a paralytic case 11 days after the first dose, and another paralytic case 14 days after the first dose.

In each instance in which the site of the injection and the site of the first paralysis is known, the latter occurred either in the limb injected, or in the corresponding limb of the opposite side; in other words, the cells of the spinal cord first involved were at the same level as the injection. The anatomists tell us that the lymph streams accompanying the peripheral nerves do not enter the vertebral canal, so that there is no direct connection between the blood or lymph supply of a limb and the corresponding level of the spinal cord. These cases would therefore tend to show, what experimental work has already indicated, that the virus of poliomyelitis travels along the nerve fibers themselves.*

---

* At a luncheon session of the Health Officers Section of the American Public Health Association at the Sixty-fourth Annual Meeting in Milwaukee, Wis., October 10, 1935. Dr. Leake mentioned a fatal case occurring 14 days after the first and only dose of another vaccine, as possibly being parallel to the cases above cited. Since then 2 other paralytic cases have occurred 13 and 14 days, respectively, after administration of the same vaccine. While any one of these alone would be dubious, the periods of time between vaccination and onset, in connection with the series above cited, appears to justify discontinuance of the human use of this vaccine also.

NOTE: For details of cases mentioned, see *J.A.M.A.*, Dec. 28, 1935, p. 2152.

An Improved Method of Preparing the Kolmer Poliomyelitis Vaccine*

JOHN A. KOLMER, M.D., D.Sc., LL.D. †

Professor of Medicine, Temple University, and Director of The Research Institute of Cutaneous Medicine, Philadelphia, Pa.

IN the preparation of poliomyelitis vaccine by the method of Kolmer[1] 8 gm. of remote monkey passage spinal cord are thoroughly emulsified aseptically in 100 c.c. of sterile saline solution. After fine-mesh filtration to remove coarse particles, there is added an equal volume of sterile 2 per cent solution of sodium ricinoleate (William S. Merrell Company) which gives a 4 per cent suspension of virus in 1 per cent sodium ricinoleate. This mixture is placed in an incubator at 37° C. for 24 hours and then in a refrigerator at 10° to 12° C. for 10 to 14 days, with daily shaking for a few minutes, when aerobic and anaerobic cultures are made and mice injected intraperitoneally as an additional test for any possible contamination with tetanus bacilli or spores. When a careful aseptic technic is employed, the great majority of the vaccines are found to be sterile.

PURPOSE OF INVESTIGATION

Since sodium ricinoleate is of low bactericidal activity, care is required against subsequent accidental bacterial contamination of the vaccine, especially during its administration. For this reason we have sought to determine if it is possible to add germicidal agents in bactericidal amounts without reducing the immunizing capacity of the vaccine, in order to prevent accidental contamination, such as has occurred in a few instances, with the production of severe local reactions at the sites of inoculation.

Since we are convinced that the immunizing value of the vaccine depends upon the presence of living attenuated virus, this has meant the possibility of finding a chemical agent capable of selectively destroying such organisms as staphylococci, streptococci, *B. coli,* and *B. subtilis,* without materially destroying the virus, since these organisms are of most importance from the standpoint of possible contamination in the preparation and administration of the vaccine.

For this purpose we have contaminated portions of sterile vaccine with these organisms and determined the approximate smallest amounts of formalin, phenol, mercurophen, merthiolate, and phenyl-mercuri-nitrate capable of sterilizing in an exposure of 24 hours at 37° C. We conducted the tests with the finished ricinoleated vaccine with an exposure of 24 hours at 37° C. in order to duplicate exactly practical working conditions in the preparation of the vaccine, as well as to include the bactericidal activity of sodium ricinoleate and the influence of the spinal

---

* Read before the Laboratory Section of the American Public Health Association, at the Sixty-fourth Annual Meeting in Milwaukee, Wis., October 8, 1935.

† With the assistance of Anna M. Rule.

cord protein in reducing the bactericidal activity of the chemical agents employed.

As soon as the bactericidal activity of the 5 chosen agents for the 4 organisms was determined, we prepared 5 ricinoleated vaccines exactly as outlined except that 1 carried the *minimum* bactericidal concentration of formalin, a second phenol, a third mercurophen, a fourth merthiolate, and a fifth phenyl-mercuri-nitrate. These 5 vaccines were employed in the immunization of monkeys to determine whether the antiseptics had caused any reduction in their vaccinogenic activity.

Another factor which has engaged our attention is the possibility of *Macacus rhesus* monkeys harboring in the central nervous system the virus of lymphocytic choriomeningitis described by Armstrong and his colleagues[2, 3, 4] and which they believe may produce a benign type of so-called "aseptic meningitis" in human beings. Fortunately, according to these investigations, it is possible to detect the virus in the brain and spinal cord of monkeys by intracerebral inoculation of mice and guinea pigs. We have included this test routinely on all monkey poliomyelitic spinal cords and brains before using the former in the preparation of vaccine. We have not encountered the virus in a single animal.

BACTERICIDAL TESTS

Tests were conducted with formalin (U. S. P.), phenol (U. S. P.), mercurophen (Sharp & Dohme), solution 45 of merthiolate 1:1,000 (Lilly Co.), and phenyl-mercuri-nitrate (Merrell Company). One hundred c.c. portions of finished sterile ricinoleated vaccine were contaminated with 1 c.c. of a 24 hour broth culture of *Staphylococcus pyogenes aureus* and 1 c.c. amounts added to 1 c.c. of dilutions of formalin 1:1,000 to 1:6,000, giving final dilutions of 1:2,000 to 1:12,000. These were thoroughly mixed and placed at 37° C. for 24 hours, when 0.5 c.c. of each was sub-cultured in 200 c.c. of nutrient broth, in order to dilute the formalin carried over well beyond its bacteriostatic threshold. These sub-cultures were incubated for 3 days when the results were recorded. At the same time duplicate tests were conducted with ricinoleated vaccine contaminated with similar amounts of 24 hour broth cultures of hemolytic streptococcus, *B. coli*, and *B. subtilis*. Phenol was used in final dilutions of 1:80 to 1:400; mercurophen and merthiolate in 1:30,000 to 1:160,000; and phenyl-mercuri-nitrate in 1:40,000 to 1:240,000 in similar tests with the 4 organisms.

The results summarized in Table I show the bactericidal activity of the 5 agents for the 4 organisms according to the technic employed. The tests were conducted 3 times, and while the results were not identical, yet those shown are, we believe, approximately correct. The streptococcus was most easily destroyed. The staphylococcus ranked next in susceptibility to all 5 agents, while the colon bacillus was more resistant than *B. subtilis*, probably because sodium ricinoleate has a peculiar bactericidal and bacteriostatic activity for this spore-bearing organism.

The mercurial compounds were most bactericidal. Phenyl-mercuri-nitrate gave the best results followed by mercurophen, merthiolate, formalin, and phenol, in the order of bactericidal activity.

PREPARATION OF VACCINES

Five ricinoleated vaccines were then prepared of monkey poliomyelitic spinal cord as previously described[1] except that the solution of sodium ricinoleate carried twice the minimal bactericidal amounts of the 5 germicides, the amounts employed being:

RESULTS OF IMMUNIZATION OF MONKEYS

Six monkeys were used for each vaccine; 2 received 0.05 c.c. per kg. subcutaneously every 5 days for 5 doses, 2 0.25 c.c., and 2 0.5 c.c. Twelve days after the last dose each animal received an intracerebral injection of 0.5 c.c. of 5 per cent virus (about 10 minimal infective doses) as a test for acquired immunity, and all animals were kept under daily observation for 4 weeks.

Six additional monkeys were immunized with the ricinoleated vaccine alone as controls, and 4 monkeys received an intracerebral injection of the virus alone at the time the tests for immunity were conducted as controls on the infectivity of the virus. The results are summarized in Table II.

All of the 4 monkeys receiving intracerebral injections of the virus alone

* Every 5 days by subcutaneous injection for 5 doses.
† 0.5 c.c. of 5 per cent virus (about 10 minimal infective doses) given 12 days after last dose of vaccine.

developed severe paralysis 7 to 8 days after inoculation.

None of the monkeys developed paralysis from any of the vaccines alone, even in doses as large as 0.5 c.c. per kg. This confirmed our previous observations that subcutaneous injections of virus treated with sodium ricinoleate has not produced poliomyelitis in monkeys, even though the strain employed has been well adapted to this animal.

The best results were observed with the regular ricinoleated vaccine without the addition of any germicide, since all of the monkeys receiving 0.25

and 0.5 c.c. per kg. for 5 doses were completely protected against the intracerebral injection of about 10 minimal infective doses of virus. Those receiving 0.05 c.c. per kg. probably had a slight degree of immunity since paralysis did not appear until 11 to 14 days after intracerebral inoculation with virus, whereas the unvaccinated controls developed paralysis on the 7th and 8th days. A monkey inoculated intracerebrally with 0.3 c.c. of the vaccine developed paralysis 10 days later, indicating that the vaccine contained living but probably slightly attenuated virus.

None of the monkeys receiving the formalized vaccine were protected. We do not know whether the virus was completely killed by the amount of formalin used, but certainly the doses of this vaccine employed were insufficient to engender a protective degree of immunity to the intracerebral injection of the 10 minimal infective doses of virus employed as a test for acquired immunity. In this connection it may be stated that a monkey inoculated intracerebrally with 0.3 c.c. of the vaccine remained perfectly well, indicating that the virus was either killed or greatly attenuated. It may be that larger doses per kg. of weight would have engendered an immunity, but none was apparent with the amounts employed.

With the phenolized vaccine both monkeys receiving the 0.5 c.c. dose developed effective immunity. With the 0.25 c.c. dose some immunity was apparently produced because paralysis did not develop until the 12th to 14th day after intracerebral inoculations of virus; but those receiving the 0.05 c.c. dose apparently developed no immunity at all. A monkey inoculated intracerebrally with 0.3 c.c. of this vaccine developed a slight degree of paralysis of the right arm 18 days later, indicating that the vaccine contained a small amount of living virus which probably accounted for the immunity engendered by the larger doses.

The vaccines carrying mercurophen 1:40,000 and merthiolate 1:40,000 engendered complete protection in the 0.5 c.c. doses. Some immunity resulted from the 0.25 c.c. dose, but undoubtedly the addition of these agents in concentration of 1:40,000 reduced to some extent the immunizing value of the ricinoleated vaccine.

That these agents, however, produced some slight destruction or attenuation of the virus is indicated by the fact that monkeys inoculated with 0.3 c.c. of each vaccine did not develop paralysis until 14 days later, whereas the ricinoleated vaccine produced paralysis in 10 days.

The results with phenyl-mercurinitrate vaccine were much better, probably because of less attenuation or destruction of the virus, since a 1:80,000 concentration was employed. Not only did both monkeys receiving the 0.5 c.c. dose escape infection, but also 1 receiving the 0.25 c.c. dose, while the second animal receiving this amount did not develop paralysis until the 21st day after intracerebral injection with virus. Furthermore, a monkey inoculated intracerebrally with 0.3 c.c. of this vaccine developed paralysis on the 9th day, indicating that phenyl-mercurinitrate in the amount employed produced no further attenuation of the virus than that produced by sodium ricinoleate.

The results have shown that the addition of 1:4,000 formalin to the vaccine results in so much destruction of virus as greatly to reduce its immunizing value. The same was found true but to a lesser extent with vaccine carrying 1:100 phenol. In other words, it would appear that approximately twice the smallest amounts of these agents required for the destruction of staphylococci and colon bacilli in

ricinoleated vaccine produce too much destruction or attenuation of the virus for effective immunization. It may be that larger amounts of these vaccines than those employed may produce some degree of immunization, but certainly not in the doses employed which, however, were highly effective with the ricinoleated vaccine.

Best results were observed with phenyl-mercuri-nitrate. Its addition in 1:80,000 dilution to ricinoleated vaccine appears sufficient for bacteriostatic and bactericidal purposes, although even this small amount may very slightly reduce the immunizing capacity of the vaccine. Mercurophen and merthiolate rank second, but must be used in a concentration of 1:40,000 and this amount more definitely reduces vaccinogenic activity. It is likely, however, that this reduction can be overcome by making the doses slightly larger than those employed with the plain ricinoleated vaccine and that carrying 1:80,000 phenyl-mercuri-nitrate. In general we believe that the results confirm the observations of others and ourselves that the maximum of immunization is to be obtained with vaccines showing the minimum destruction or attenuation of the virus.

The plain ricinoleated vaccine in the doses employed[5] produces only slight local reactions at the sites of injection. In several instances where marked local reactions have followed the subcutaneous injections we have found the vaccine contaminated with staphylococci or colon bacilli. By dispensing the vaccine in individual doses the possibility of such contamination can be greatly reduced, but when dispensed in vials carrying multiple doses contamination may occur, since the 1 per cent concentration of sodium ricinoleate in the vaccine possesses very low bacteriostatic and bactericidal activity. For this reason we now prepare the vaccine with 1:80,000 phenyl-mercuri-nitrate and use it in the same doses as recommended for the ricinoleated vaccine, since the immunizing value is almost the same. Furthermore, the local reactions at the sites of injection are very slight, since this amount of phenyl-mercuri-nitrate does not appear to produce additional irritation.

VIRUS OF LYMPHOCYTIC CHORIOMENINGITIS IN RELATION TO THE VACCINE

In August, 1934, Armstrong and Lillie[2] described a neurotropic virus in monkeys, encountered during the experimental transmission of encephalitis virus from the 1933 St. Louis epidemic and which was designated as the virus of lymphocytic choriomeningitis. Subsequently Armstrong and Wooley[3] found this virus in stock monkeys and suggested that it may affect man, since 2 of their strains were possibly of human origin. In the opinion of Armstrong and Dickens[4] the symptom complex is apparently a disease entity, producing in human beings the symptoms and spinal fluid changes commonly designated as "acute aseptic meningitis" characterized by headache, fever, and meningeal irritation, with cerebrospinal fluid under increased pressure and showing an increase of cells above 50 (lymphocytes dominating), coupled with normal chlorid, sugar, and urea content, a negative Wassermann reaction, and ending in recovery with a neutralizing antibody in the blood. Mice and guinea pigs have been found susceptible to the virus upon intracerebral injection with spinal cord and brain from monkeys, the disease appearing in mice in from 7 to 12 days after inoculation, and producing convulsions with death.

Whether or not this is a new virus occurring in normal healthy stock monkeys or a virus in relationship to that of encephalitis lethargica of human origin awaits further investigation. Fortunately, as shown by Arm-

strong and his colleagues, its presence in the brain and spinal cord of monkeys can be determined by intracerebral injections of these into mice and guinea pigs, and during the past 8 months we have routinely tested the brain and spinal cord of each poliomyelitic monkey in this manner before using the cords in the preparation of vaccine.

It has been our custom to inoculate mice and guinea pigs intracerebrally with 0.03 c.c. of a 20 per cent suspension of brain and cord from each monkey, and to keep the animals under daily observation for 2 to 3 weeks. Our *Macacus rhesus* monkeys have been obtained from India and are kept under observation for about 2 weeks before inoculation with poliomyelitis virus. We have purposely kept out of the laboratories all other viruses. Up to the present we have not encountered the virus of lymphocytic choriomeningitis in a single brain or spinal cord from 84 consecutive animals, but will continue to test the brain and cord of each poliomyelitic monkey before preparing the vaccine. In this manner we believe that the danger of carrying this virus over into the poliomyelitis vaccine is removed.

IMPROVED METHOD OF PREPARING THE VACCINE

The details of preparation are as follows:

1. Healthy adult *Macacus rhesus* monkeys weighing from 4 to 5 kg. are employed.
2. The animals are kept in quarantine for 1 to 2 weeks before inoculation, preferably in isolated quarters removed from contact with other animals.
3. No one is allowed to come in contact with the animals except members of the staff, in order to reduce to a minimum any possible contamination.
4. Each animal is inoculated intracerebrally (frontal lobe) with 0.5 c.c. of a 5 per cent emulsion of monkey poliomyelitic cord (Rockefeller Institute strain) under ether anesthesia. This carries about 10 minimal infective doses.
5. Symptoms of poliomyelitis usually develop in from 7 to 10 days. Immediately after death, or when paralysis is very severe, the hair is sprayed with 5 per cent tricresol solution and the skin over the head and back removed. The cord is then removed under aseptic conditions, briefly washed in 1:1,000 water solution of mercurophen or metaphen followed by sterile saline solution and placed in a 50 per cent sterile solution of chemically pure glycerin in saline solution. The animal is then carefully autopsied for any evidences of tuberculosis. If lesions are found the cord is discarded.
6. Then 0.03 c.c. of a 20 per cent suspension of cord is injected intracerebrally into each of 2 mice; a similar amount of brain is injected into 2 additional mice. The animals are kept under daily observation for 14 days for any possible evidences of infection with the virus of lymphocytic choriomeningitis.
7. Two or more cords kept at least a week in the glycerin are used in the preparation of vaccine by thoroughly emulsifying 8 gm. in 100 c.c. of 1.6 per cent sterile saline solution.
8. After fine-mesh filtration under aseptic conditions there is added an equal volume of 2 per cent solution of sodium ricinoleate carrying 1:40,000 phenyl-mercuri-nitrate prepared as follows:

Sodium ricinoleate (William S. Merrell Co.)	20 gm.
Distilled Water	950 c.c.
Boil for 10 minutes and add:	
Phenyl-mercuri-nitrate 1.2,000	50 c.c.

This gives a 4 per cent suspension of virus in 1 per cent sodium ricinoleate and 1:80,000 phenyl-mercuri-nitrate in physiological saline solution.

9. If mercurophen is employed there is added to the 8 per cent suspension of virus an equal volume of the following solution:

Sodium ricinoleate (William S. Merrell Co.)	20 gm.
Distilled Water	950 c.c.
Boil for 10 minutes and add:	
Mercurophen 1:1,000 Aqueous solution	50 c.c.

This gives a 4 per cent suspension of virus in 1 per cent sodium ricinoleate and 1:40,000 mercurophen in physiological saline solution.

10. The vaccine is thoroughly shaken and placed in an incubator at 37° C. for 24

hours and then in a refrigerator at 10° to 12° C. for 10 to 14 days with daily shaking for a few minutes.

11. A culture of 0.5 c.c. of the vaccine is then made in 200 c.c. of broth and incubated 3 to 5 days. A mouse is also inoculated intraperitoneally with 0.5 c.c. and kept under observation for a week for any possible evidences of tetanus infection.

12. If sterile, the final test consists in the intracerebral injection of a monkey with 0.3 c.c. of the vaccine under ether anesthesia. The animal must develop some paralysis within 3 weeks. If not, the vaccine is discarded as containing virus too much attenuated and therefore too low in immunizing value for administration.

13. If sterile and containing attenuated virus, the vaccine is dispensed for administration.

14. The vaccine should be kept in a refrigerator, but even at room temperature shows no appreciable reduction in immunizing value over periods of 1 or 2 weeks. Therefore it can be shipped under ordinary conditions without the necessity of being frozen or kept at a very low temperature.

DOSAGE OF VACCINE

The dosage of the improved vaccine according to age is the same as originally advised[5] being as follows:

Under 4 years	0.25, 0.5 and 0.5 c.c.
4 to 10 "	0.5, 0.5 and 1.0 c.c.
11 to 15 "	0.5, 1.0 and 1.0 c.c.
Adults	0.5, 1.0 and 2.0 c.c.

These amounts are given by subcutaneous injection at intervals of 7 to 10 days. As is true of other vaccines, adults may show more local reaction than children and for this reason we recommend giving the third dose by injecting 1 c.c. in each arm at the same time.

ATTENUATION OF THE VACCINE

Since the vaccine contains living remote monkey passage virus the matter of its attenuation and safety for human beings has been the main issue.

While the virus is highly adapted for the monkey as the result of a very large number of passages during the past many years, it is a reasonable assumption that it may have lost thereby at least some infectivity for human beings.

The subcutaneous and intracutaneous injection of the virus is occasionally followed by the development of poliomyelitis in monkeys, as shown by Flexner and Lewis in 1910. In a series of 20 monkeys the administration of 5 doses of 0.2 c.c. of a 10 per cent suspension per kg. at 5 day intervals produced the disease in 1 animal in our laboratory. But none of a series of 42 monkeys receiving the ricinoleated vaccine in doses as large as 0.5 c.c. per kg. every 5 days for 5 subcutaneous injections has developed the disease. Under the circumstances we have concluded that keeping the cords in 50 per cent glycerol for at least a week before the preparation of vaccine, followed by treatment of the *finely divided* tissue with 1 per cent sodium ricinoleate for 24 hours at 37° C., and at least 10 days in a refrigerator at about 10° to 12° C. results in attenuation of the virus. Since the natural resistance of monkeys to intracerebral injections of virus is known to vary and especially in relation to the age and weight of the animals, it is difficult to gauge the degree of attenuation, but the intracerebral injection of 0.3 c.c. of the 4 per cent vaccine has almost invariably produced poliomyelitis in over 40 monkeys of 4 to 5 kg. more slowly than the intracerebral injection of 0.3 c.c. of a 4 per cent freshly prepared virus in control animals, and in some instances has failed to produce infection altogether over periods of 3 to 4 weeks. Under the circumstances we have concluded that the glycerin, and especially the sodium ricinoleate, produces some attenuation of the virus and that the technic of preparing the vaccine is a matter of importance in this connection. Furthermore, the addition of 1:80,000 phenyl-mercuri-nitrate or 1:40,000 mercurophen for bactericidal

purposes appears to result in some slight additional attenuation.

We believe therefore that the vaccine is safe when prepared as described, due to some attenuation of the virus, the administration of a small first dose, the rapidity of antibody production, and possibly to the fact that the remote monkey passage virus used in its preparation has lost some infectivity for human beings, as more fully discussed elsewhere.[6]

SUMMARY

1. Occasional severe local reactions following the subcutaneous injection of the Kolmer ricinoleated poliomyelitis vaccine prepared by the Research Institute of Cutaneous Medicine have been found due to accidental bacterial contamination due to the low bactericidal and bacteriostatic properties of the 1 per cent solution of sodium ricinoleate employed.

2. It has been found that the addition of 1:80,000 phenyl-mercuri-nitrate or 1:40,000 mercurophen is sufficient for protecting the ricinoleated vaccine against accidental contamination without materially reducing its immunizing properties, especially in the case of phenyl-mercuri-nitrate. The bactericidal activity of merthiolate was found slightly less than mercurophen, but a vaccine carrying this amount had the same immunizing value as that containing 1:40,000 mercurophen.

3. The addition of 1:4,000 formalin required for bactericidal effects resulted in so much destruction of virus as to render the vaccine ineffective in the immunization of monkeys in the doses employed.

4. The addition of 1:100 phenol to ricinoleated vaccine produces too much attenuation (or destruction of the virus) for efficient immunization of monkeys.

5. An improved method is described for the preparation of the ricinoleated vaccine with phenyl-mercuri-nitrate or mercurophen carrying 4 per cent attenuated virus.

6. So far, the brains and spinal cords of 84 poliomyelitis monkeys have been found free of the virus of lymphocytic choriomeningitis (Armstrong and Lillie) but the method of preparation includes a routine test of the brain and spinal cord of each monkey for this virus before the latter is used in the preparation of vaccine.

7. Sterile sodium ricinoleated vaccine with or without the addition of 1:80,000 phenyl-mercuri-nitrate or 1:40,000 mercurophen, produces only slight local reactions at the sites of injection.

8. To the best of our knowledge there have been no cases of lymphocytic choriomeningitis or demyelinization encephalomeningitis due to the administration of the vaccine.

9. While we believe the vaccine must contain living virus for effective immunization in the doses employed, its safety for human beings may depend upon some attenuation of the virus by sodium ricinoleate and phenyl-mercuri-nitrate, the subcutaneous route of administration, a small first dose along with rapid antibody production and the possibility that the remote monkey passage virus used in its preparation has lost some infectivity for human beings by subcutaneous injection.

Social Significance of Industrial Medicine*

HENRY H. KESSLER, M.D., PH.D., F.A.P.H.A.
Medical Director, New Jersey Rehabilitation Commission, Newark, N. J.

NO student of human affairs can fail to note the effects of social change on contemporary life. The present crisis has shaken to the roots our national existence, and touched every phase of our culture and civilization. Not only have our political and economic lives been affected, but the fundamental ideas and institutions controlling our every existence are being altered. The social structure of every nation is, therefore, being pitilessly scrutinized in a search for a solution of pressing national and international problems.

In the United States this examination has been directed toward an objective of material and spiritual security. To achieve this purpose successfully, a changed social mentality is necessary in view of the obligations of the new age. Obsolete concepts are no longer applicable in the explanation and control of modern problems. The transition of American civilization from its pioneer stage to its integrative and cultural stage, has necessitated a redefinition of established institutions and ideas.

Disease and medicine are two concepts that have a profound influence on our individual and collective welfare. The strength and health of a nation are made up of the vigor of its composite units, individuals and families. These values can only be maintained effectively by having them keep pace with the general progress in society. To achieve this goal, these concepts must be modified to fit in with the needs of the changing order.

Medicine has been defined as the science and art which deal with the prevention, cure, and alleviation of disease. As a science, medicine seeks to understand the problems underlying disease. As an art, it applies the knowledge thus gained to the solution of medical problems.

Primitive theories concerning disease were developed either from experience or from an animistic-religious point of view. The first hygienic rules were associated with the religious rites of early civilization. Following the discovery of the circulation and the scientific discoveries of the 17th and 18th centuries, disease was viewed as a biologic phenomenon due to morbid changes in life forms. This biologic aspect has been emphasized by the marked advances and discoveries in pathology and bacteriology during the 19th century. Disease then is regarded as a disturbance in the equilibrium of psychosomatic forms and functions.

The extreme difficulty, however, of studying the internal balance of the organism divorced from its environment has necessitated a new point of view.

---

* Chairman's Address, read before the Industrial Hygiene Section of the American Public Health Association at the Sixty-fourth Annual Meeting in Milwaukee, Wis., October 7, 1935.

This view seeks to interpret the organism cosmically, and thus subject to the many interacting forces derived from the world in which it lives. In this sense the organism and its internal and external environment are considered as a whole.

Despite progress in the control of communicable disease thousands of people still die every year in all countries from preventable disease. Millions still suffer from tuberculosis in spite of our modern knowledge of its prevention and treatment. The average worker has a shorter life expectancy than the non-worker. Young children are still crippled annually by rickets, although this disease can be prevented. Thousands of women die annually from septic abortion because it is immoral to obtain contraceptive information. Such apparently unrelated factors as the curtailment of contraceptive advice and the reduction of public health budgets have a common effect in influencing the incidence and progress of disease. These inconsistencies are due to the operation of social forces.

Disease then becomes a problem of society like vice, war, crime, poverty, and unemployment. If we regard society as an organized system of human relationships, we find that its integrity is being constantly threatened by these crises. Society defends itself by calling upon safety factors within its own structure to correct the threats upon its unity. A study of the adjustment of society to its medical problems may furnish clues to the prevention, treatment, and alleviation of disease, a point of view not adequately stressed in the purely biologic approach to the problem.

Medicine then may be regarded as a social science, for both medicine and sociology as science and art have a common aim—the protection of human beings in society. The study of medical and social problems is the scientific phase. The practice of medicine and social work is the artistic. In the United States, the scope of social medicine has never been adequately defined. Broadly the term has been applied to any field of medicine presenting casual social factors.

Social medicine may be defined therefore as that field of medicine which, viewing disease as both social and biologic, attempts to determine the social cause of disease and to devise social means of prevention, cure, and alleviation. It is, therefore, a large field which covers social causation and diagnosis, social therapy and prophylaxis.

One of the contemporary leaders in the development of this science called social medicine is Zannger of Zurich, whose conception of social medicine is based on a broader idea of the subject of preventive medicine as it is taught in universities. According to Zannger, social medicine is related to legal medicine but not identical with it, and neither subject is identical with preventive medicine. His concept developed out of his experience in the scientific study of hazards in plants and industries. By studying the diseases caused by industrial activities and industrial accidents, by learning how to prevent accidents, and how to help the working class in protecting their health, he developed a new concept of social medicine from a medical point of view.

Social medicine from this point of view further notes the effects of unemployment on mortality, and the influences exerted by an occupation on the health of an individual. Social medicine studies the legislative and economic measures capable of diminishing the consequences of disease. These social phenomena are in a constant state of flux. What was true yesterday may no longer be true tomorrow. The leaders in social welfare should therefore endeavor to look into the future,

while university instruction should also take account of these facts.

From the time of Ramazzini, when he first called attention to the important relationships between conditions of work and the state of health, to the present, social medicine has gradually evolved into its present broad concept. It is now held to comprise all of social hygiene, legislation, the study of sociological, political, economic, and pedagogic factors, which permit its organization and its extension throughout the world.

There are two aspects of social medicine: first, the study of social factors as the cause of disease, and second, the use of social methods in the control of disease.

Except for industrial medicine, social factors as a cause of disease have been given little emphasis. Other environmental factors such as income, housing, and nutrition have been given superficial consideration.

Social methods in the control of disease, however, are well developed. Social medicine was born when communities were sufficiently organized to contain a centralized authority, well versed in the needs of the people and prepared to meet these needs with social defenses. These social defenses may be seen in such measures as social hygiene, socialized medicine, social insurance medicine, and medical social work.

The term "social medicine" has been frequently identified with these concepts of social hygiene, socialized medicine, social insurance medicine, and medical social work, but, as we shall see, it includes these various concepts yet is more comprehensive in its connotation.

Social hygiene, preventive medicine and public health are 3 identical concepts in the field of medicine that have been growing rapidly in importance in the last 30 years. Their theory is built up by the search for the relationship between environment and health; while in practice these disciplines promote and maintain the public health. The control of communicable disease, the improvement of water and milk supplies, the control of sewage disposal, and improved working conditions have had their effect on personal and community health. The population growth in Japan, for example, from 40,000,000 inhabitants in 1900 to 72,000,000 in 1935, is due in great part to the introduction into Japan of the western method of hygiene.

By socialized medicine is meant the distribution of medical service, so as to care for large numbers of people. This movement may manifest itself in many forms. State medicine, one of these forms, is a generic term and refers to any system of medical care provided by State salaried physicians. In its restricted and more usual meaning State medicine is thought of as the furnishing of medical care by the State to certain vocational groups of geographical areas. Physicians in the army or in Indian reservations, for example, practise State medicine.

Contract medicine, another form of socialized medicine is the furnishing of medical care by a physician whose income is fixed by contract. Such contracts are usually made by industrial and business enterprises, and the salary of the physician is more or less independent of the number of patients that he treats. Small communities sometimes engage the service of a physician on a contract basis, the doctor's income being derived either from the public treasury, through taxes levied on the potential patients, or from a fund accumulated by the contributions of the subscribers.

Social insurance medicine, which has been given some consideration in this country since the introduction of the workmen's compensation law, and the

anticipated introduction of sickness insurance schemes, is also a form of socialized medicine described above.

Through the insurance principle the economic risks of illness are distributed among the general population. In some countries such health measures exist on a purely voluntary basis; in others all citizens falling within certain income groups, are legally obliged to participate in the insurance plan.

Social medicine is frequently confused with medical social work. The latter is merely the application of social case work to medical service. Both are based, however, on the same hypothesis that disease and defect are never isolated but exist in a complex of personal and environmental conditions. Since these conditions may favor or hinder recovery they must, therefore, be taken into account in the treatment of illness.

Industrial medicine provides the only social orientation in American medicine. It recapitulates all the elements of social medicine, both theoretical and practical. On the theoretical side it studies the industrial environment as a causative factor in disease. On the practical side it employs all the measures of control found in social medicine.

In industrial hygiene we see the application of measures to control the industrial environment in order to prevent disease and maintain the health of the worker.

Socialized medicine is noted in the furnishing of partial and sometimes complete medical service by industry to its employees.

Social insurance medicine has its counterpart in American workmen's compensation schemes, where we find the economic risk of occupational illness and accident distributed among the general population by absorption in the cost of the finished product. In workmen's compensation we find represented forms of social insurance other than that of accident insurance. Sickness insurance, may be seen in the compensation for the aggravation of preëxisting disease. Workmen's compensation may appear to represent unemployment insurance, when injured workmen prolong their disability period over the stage of healing and repair. These men are being paid for being unemployed and not for being disabled. Old age insurance is represented by the fact that aged workers receiving minor injuries are frequently disabled totally and permanently because of their age and not because of their injury.

Medical social work is well developed in industry, with and without organized social welfare departments.

Thus we see how social medicine in theory and practice is applied to a large element of our population. This working group must not be looked upon as a special class, since today it forms the larger proportion of our entire population. The farmer is here also included since the mechanization of agriculture has changed the latter's status from that of a peasant to a worker.

The social significance of industrial medicine, therefore, is of extreme importance. Limited in the past to scattered services and an unimportant place in American medicine, the time has now come where its relationship to social medicine must take a more complete and definite form. This can only be done by a correlation of all the services and activities in the field of industrial medicine as it relates to the larger field of social medicine. The physician, the research worker, the university, the employer, the worker, and government must pool their resources and their efforts in creating a national fund of knowledge and practice, from which all who are dependent upon this information, must draw. Such a coordinated point of view demands an instrument for its achievement. This

instrument that I propose is a national institute of industrial medicine.

Many European countries have given expression to their appreciation of the social significance of industrial medicine by the creation of occupational disease institutes and safety museums. In our own country the National Safety Council was established for the purpose of educating the public to the importance of the industrial environment as a factor in illness, and in practical measures of controlling this environment. In the international sphere the value of a central agency for the promotion of the study of the adjustment to conditions of industrial life and labor led to the creation of the International Labour Office.

The latter exists as an international clearing house for the distribution of information with respect to the living conditions and employment of the workers. The disadvantage of that agency, however, in its application to our needs is, in the first place, that it is too remote geographically, and, secondly, there are too many political considerations which revolve upon its existence. The National Safety Council has a remarkable history of achievement; yet, its effectiveness has been limited by its narrow scope. There is, therefore, a real need for the creation of a national institute of industrial medicine in this country, designed to study the industrial environment as a cause of disease and the measures of social control to prevent, alleviate, and eliminate disease.

Such studies may be broadly classified into 4 categories: (1) the promotion of education, (2) the promotion of research, (3) the promotion of legislation, (4) the development of standards.

EDUCATION

Education in social medicine in which industrial medicine forms a large background, may take several forms. To begin with there is a dearth of studies in the medical curriculum with respect to the social sciences. It is appreciated that the present-day curriculum in medical schools is already overburdened. There is no reason, however, why such social studies as vital statistics, social hygiene, and economics, cannot be included in the premedical school years.

There is a great need for the extension of present-day instruction in industrial hygiene in medical schools. At present, of 85 medical public health schools in the United States and Canada surveyed by Bristol in 1934, only 13—10 medical and 3 public health—give separate courses in industrial hygiene; 24 medical schools add one or more special lectures in their general public health and hygiene courses; 18 schools give only brief attention to industrial hygiene; and another 21 apparently give no instruction in industrial hygiene. Regardless of the ultimate objectives of medical students, the social significance of industrial medicine makes it desirable to intensify undergraduate instruction in industrial hygiene.

There is also need for postgraduate instruction in industrial hygiene. This may take several forms: (1) specified courses of instruction in well equipped schools of public health, or specially created institutes, or (2) courses of study in large industrial centers for the practitioner who lives in a community where industrial health hazards are a special medical and social problem.

To overcome the reduction in the life expectancy of the average worker it is desirable that preventive work be promoted. While safety education in industry has achieved a phenomenal success in the reduction of accidents, health education in industry has failed completely in making the worker conscious of any responsibility in the

maintenance of his own health. The same technic that has been so successful in combating accidents, bringing the responsibility for accidents down to the lowest executive unit, the foreman, can be applied to industrial health education. It is this same technic that has made child health education successful by making the parent, the nearest executive unit, participate through the medium of Parent Teacher Associations.

Here then are 2 aspects of education in industrial medicine that require the support and development of a national advisory group: (1) the improvement of the equipment of those who protect the health of the industrial community, and (2) the education of the industrial worker in the care and protection of his own health.

RESEARCH

An important objective of a national institute of industrial medicine would be a clearing house of information. Such an institute would distribute this information by direct correspondence in answer to specific inquiries, by the publication of an annual bulletin and special reports.

A special function of this institute would be that of research. Here problems could be worked out from clinical, chemical, industrial, insurance, pathological, and other aspects. This does not mean that all phases of an industrial problem would be studied in one institute, but that research in these various fields could be directed to those agencies or institutions best equipped to carry them out. In this manner present-day mistakes could be avoided, namely, the duplication of effort, the carrying on of research by inadequately equipped organizations, and the failure to utilize properly equipped agencies already existing. The Du Pont Company today has an exceedingly well equipped laboratory, for the study of the toxocologic properties of their manufactured products. Many a manufacturer would consider himself very fortunate to be blessed with such a laboratory. The manufacturer of new products, unfamiliar with their physiological effects distributes his products today with a great deal of trepidation, in view of the rising incidence of litigation. There is, therefore, less reluctance on the part of these employers to survey the health problems involved in the manufacture of their products and also in the analysis of their physiological effects. A small manufacturer would appreciate knowing where his products could be studied at a small cost, or would even be willing to contribute to the support of such a central laboratory.

LEGISLATION

Ever since the law written on two tablets of stone was given to Moses on Mount Sinai, legislation has been an ideal for the expression and safeguarding of the common standards of life and conduct with authority to achieve a larger measure of social justice.

The control of widespread social evils, such as poverty, dependency, sickness, disability, and delinquency by social agencies and voluntary action has been very difficult. Their experience is valuable as a laboratory experiment to show the futility of such action. Such a law as Mothers' Pensions has helped to simplify the work of social agencies in the solution of the problem of dependent children and widows. Workmen's compensation has ameliorated the disabling effects of accident. Child labor laws have reduced mortality and disability and have given children greater psychological and social opportunity. All these objectives of social welfare promoted by social agencies have been achieved by legislation.

The basis of all legislation must be

accurate data. It is important that the legislator be supplied with information not only about the statute law of his own country and state, but also about the condition of the law and the course of legislation on the subject with which he deals in other countries and in neighboring states. For this purpose bill drafting and legislation reference bureaus have been established.

Some years ago the Wisconsin legislature voted a small appropriation for a legislative reference library, and a man carefully trained in history, economics, and political science was put in charge. With a small expenditure he rapidly gathered a valuable collection of reports, bills, and laws; catalogued and indexed them, so as to be at all times available. When the legislature convened he was ready to give every legislator important service and reliable information. No matter what subject a member might be interested in or what bill he might be desirous of introducing or fighting, he need not be at a loss as to what other states had done, how such legislative experiment had succeeded, and how to frame his own proposals. Bills were drafted for members at their own request and they were given hints on important points of practice and even arguments were prepared for them, if they wished.

The American Association of Labor Legislation has served in a similar but less comprehensive capacity for all labor legislation including that on occupational disease. Our own standards committee of the Industrial Hygiene Section has carried on a similar function in the field of occupational disease legislation. There is room and need for an expansion of such a service under the supervision of a national advisory group like a National Institute of Industrial Medicine.

STANDARDS

The rising incidence and costs of litigation in the field of industrial medicine, both under common law and workmen's compensation administration, has stimulated the formation of fly-by-night groups interested in the correction of the abuses arising out of this litigation. One of the most important abuses arises in the use of experts for court testimony. There is no agency fit to pass on the qualifications of those who are called as experts to testify in cases of occupational disease, be they engineers or physicians. It is desirable that such qualifications be established and that a panel of qualified medical and non-medical experts in industrial medicine be created under the supervision of this national institute of industrial medicine. Certification by this body would do much to correct one of the primary abuses in expert testimony.

SUMMARY

I have attempted to stress the social significance of industrial medicine and have suggested a device or agency the creation of which will materially assist in correcting some of the maladjustments in our present social crisis. If the conditions in which we live are to be improved and if social progress is to be realized, it must be within the system of the industrial order in which we live.

Efficiency of Methods and Products for Sterilization of Beverage Glasses*

E. D. DEVEREUX, PH.D., AND W. L. MALLMANN, PH.D., F.A.P.H.A.

Department of Bacteriology and Hygiene, Michigan State College, East Lansing, Mich.

A SANITARY survey was made of establishments dispensing beer in Lansing, with the aim of introducing practical procedures for cleansing and sterilizing glassware. The procedure recommended is to wash the glasses free from any retained beer, using running tap water; they should then be rinsed in a disinfectant or rinsed and allowed to drain, for the recommended period of time to effect sterilization. For chlorine sterilizers, the most suitable compounds, 5 minutes is recommended. Following sterilization the glasses may again be rinsed in clean running water.

In the laboratory *Escherichia coli* and *Staphylococcus aureus* were independently introduced into solutions of various disinfectants. The numbers of organisms surviving after exposure of 15, 30, 45, 60, 90, 120, and 180 seconds and 5 and 30 minutes were determined by plate counts.

Sodium chloride and trisodium phosphate have been recommended for sterilizing beverage glasses. However, 5 per cent sodium chloride solution or 1 per cent trisodium phosphate was found unsuitable. Calgonite, a detergent containing sodium metasilicate, when used in a concentration suitable to the hardness of the water employed, was capable of destroying *Esch. coli* in 15 seconds; however, it had little or no effect on *Staph. aureus* in 30 minutes. Because of the apparent selective action of this compound it cannot be recommended as a disinfectant agent.

Klemm's Cleaner, a disinfectant, was found capable of destroying the test organisms in approximately 2 minutes. A very significant reduction was effected in 1 minute. However, this compound has questionable value because it produces an intense purple color and stains utensils.

Natraphene, sodium 2 — hydroxy diphenyl, has been suggested for the sterilization of beverage glasses. This compound when used in the recommended concentration of 1 to 1,000 was very slow in destroying *Staph. aureus* and *Esch. coli*. The retarded action of this compound with the lack of a suitable test for determining its concentration makes it undesirable.

Of the chlorine containing compounds examined those containing inorganic chlorine were found to be more suitable because of the speed of reaction. Two hundred p.p.m. is recommended. A more detailed discussion of these preparations was presented in a previous paper.[1] A new chlorine preparation, Azochloramid, was found to be comparable to chloramine T in its killing speed. The compound, like chlora-

---

* Read before the Food and Nutrition Section of the American Public Health Association at the Sixty-fourth Annual Meeting in Milwaukee, Wis., October 10, 1935.

mine T products, may be used for beverage glass sterilization provided a sufficient period of exposure is used. This preparation has the added advantage that the yellow color produced is indirectly a measurement of the available chlorine present.

Hot water, as employed in a mechanical dish washer, has been found to be very satisfactory in sterilizing glasses. A minimum temperature of 160° F. (71° C.) should be maintained. On repeated tests all glasses examined were found to be free from organisms.

A device using ultra-violet light as the sterilizing agent was submitted for examination. The machine was designed to sterilize the rim of the glass while the glass was being filled. Laboratory tests disclosed the fact that the time required to effect sterilization of the rim of the glass was greatly in excess of the time required to fill the glass.

In summarizing these findings it was obvious that the most effective agents were hot water, and the sodium and calcium hypochlorites. Azochloramid and chloramine T were suitable providing the time of exposure was sufficiently long. While Klemm's Cleaner was found to be an effective disinfectant it was unsuitable because of other physical properties. Sodium chloride, trisodium phosphate and Calgonite were unsatisfactory.

The ideal beverage glass sterilizer is one which is not toxic to man, is not obnoxious in any manner, does not possess any undesirable physical characteristics, does not produce a precipitate, effects sterilization rapidly, and one the concentration of which can be easily determined.

Group Payment for Hospital Care in New York

AFTER two and one-half years of study and preparation, which involved the enactment of an amendment to the insurance law of the State of New York, the Associated Hospital Service was incorporated in 1934 to undertake a plan of group payment for hospital care. The initial expenses of organization and promotion were met by grants from the Commonwealth Fund and the Josiah Macy, Jr., Foundation.

A campaign of public education undertaken by the United Hospital Fund's Department of Education has made the public widely familiar with the benefits of this "3¢ a day" plan. The public response to the plan was so enthusiastic and the approval of it so widespread, that in less than six months the quota of subscribers for the entire first year was exceeded. While the results have been gratifying, it cannot be expected that the volume of business will be sufficient for several years to appreciably affect hospital income, the plan being in no sense a money-making scheme for hospitals. It is rather a public service made available to persons of modest means by the hospitals.

Shellfish Report from the Standpoint of the Control of Shellfish in Interstate Shipments*

ALBERT C. HUNTER, PH.D., F.A.P.H.A.

Senior Bacteriologist, Food and Drug Administration, U. S. Department of Agriculture, Washington, D. C.

IN applying standard methods for the bacteriological examination of shellfish, the food law enforcing officer has an objective quite in common with that of the sanitary engineer and the public health official who exercise control over sanitation surrounding production. Because of differences in jurisdiction and legal authority, the agency supervising interstate traffic must adopt control procedures different from those employed by supervisors of sanitation at the source of production. If a method of analysis is to be useful in any plan of control of interstate commerce, it should be devised to present data essential for such control under the limitations of authority imposed by the terms of the applicable law.

A brief sketch of the methods of control possible of application by agencies supervising production, and those enforcing interstate food laws will bring out more clearly existing differences of jurisdiction and authority. Since the public health officer in the producing state has ready access to the oyster growing areas he can conduct sanitary surveys of the surrounding terrain, examine bacteriologically the waters in the growing areas and inspect shucking houses. In conformity with compliance, or non-compliance with a sanitary code, the public health officer may grant or refuse certificates permitting production or licenses allowing shipment and sale. This official has power to approve or condemn entire areas of production.

In contrast to this method of control at source of production, the organization controlling interstate shipments must proceed by the objective examination of samples collected at destination, or, at best, after the shellfish have been offered for shipment. Only in a limited manner can sanitary surveys of growing areas be made. The present federal food and drugs act contains no quarantine, or embargo power, and does not provide for the issuance of licenses, or permits. While the Food and Drug Administration, for the guidance of sampling operations, does inspect food establishments, no sanitary code for oyster shucking houses is provided. In applying the food and drugs act to oysters each shipment must be considered as a single case, and the action indicated must be based on the data available relative to the individual

* Read before a Joint Session of the Laboratory, Food and Nutrition, and Public Health Engineering Sections of the American Public Health Association at the Sixty-fourth Annual Meeting at Milwaukee, Wis., October 8, 1935.

shipment. The control procedure laid down in the federal food and drugs act is a process of seizure by libel of those goods which have been found to violate the law. In the sanitary control of oyster shipments, this calls for an allegation by the government that the product is filthy, or dangerous to health, and the burden of proof then rests upon the libellant to sustain these allegations.

Therefore, it is apparent that the soundness of the analytical method becomes a vital factor in the successful control of interstate shipments which are violative of the law. A standard method of examination meeting with general approval, and presenting data interpretable in irrefutable terms of filth, or danger to health, is a weapon sorely needed by the official responsible for control of interstate shipments.

Inquiry by the Referee on Shellfish Examinations has brought forth the information that in routine practice in nearly all those laboratories to which questionnaires were directed, the present standard methods [1] are being used essentially as given, with only minor variations. This might be construed as an indication that the present standard methods meet with rather universal approval. However, certain critical reports [2, 3] on the significance of the *Bacillus coli* score, the skepticism often expressed regarding the use of only shell liquor for examination, and questions raised relative to the inclusion of so-called non-fecal members of the coli-aerogenes group in computing the score, lead to the conclusion that there is no such universal approval, and that the methods as given are often followed simply because they are designated as "standard."

The unit of measurement of pollution in oysters provided in present standard methods, and the only guide available to the analyst, should his information be restricted to the results of examination of a sample, is a score arrived at by an arbitrary numerical system based on the prevalence of all members of the coli-aerogenes group. It is known that in addition to the amount of pollution present, the score is affected by hazards of sampling, seasonal variation in the bacterial content of oysters, methods of handling, and vicissitudes of transportation. It must be borne in mind that the analyst functioning in the enforcement of food laws obtains for his sample oysters, not taken directly from the growing areas, but from shipments which have been subjected to the influencing factors mentioned. It has been generally accepted that bacteria of the *B. coli* group do not tend to multiply in shell oysters after removal from the water if the oysters are maintained alive. However, reports not infrequently made of high scores, at shipment destination, in oysters from approved areas serve to confuse the administrator and becloud the significance of the score. In most cases the score, as determined in the present standard methods, for the purposes of control of interstate shipments, must be supplemented by information regarding sanitary conditions at source of production, and by some knowledge of the conditions of handling. The need for such information, which may not always be at hand, may result in embarrassment in the effectual carrying out of the purposes of the law. This condition indicates the necessity for some more definite means of measuring pollution than is prescribed in the present system of scoring.

The interpretation of the *B. coli* score on shucked oysters examined at shipment destination presents a particularly vexing problem. Recognizing that shucking operations and shipping conditions tend to disturb any correlation that might exist between *B. coli* score on shucked oysters and sanitation of the growing areas, it is extremely difficult to translate the score obtained

by present methods at destination, into terms of potential danger to health. It is particularly important that this phase of shellfish examination be given attention and study. Since shucked oysters are invariably shipped under refrigeration, which, if properly conducted, should provide temperatures below 50° F., it is possible that a differential score, based on the prevalence of fecal *B. coli*, may have greater significance than does the score determined by the procedure given in the present methods.

Standard methods[1] recommend the discontinuance of the determination of total counts of bacteria in the shell liquor. Perry[3] has shown that total counts are a better index of cleanliness in handling than is the *B. coli* score on shucked oysters when determined at the shucking house. From the standpoint of the control of interstate traffic, however, total counts, because of their variability and wide range, when determined on samples from shipments, cannot be relied upon to serve as sole evidences of unfitness. If determined as an optional procedure with shucked oysters, they may provide the food control official with some evidence regarding the general cleanliness of the product.

Legal actions under the present federal food and drugs act against shipments of polluted oysters must be based on charges that the product is filthy, or dangerous to health. In considering the sufficiency of analytical evidence to substantiate such charges, a question arises regarding the interpretation to be placed on the presence of the various members of the coli-aerogenes group. There should be no controversy concerning the significance of organisms confirmed as fecal *B. coli*, whereas there may be almost unlimited argument relative to the significance of other bacteria of the group. Therefore, in determining a course of action following the accumulation of analytical, as well as inspectional data, it is decidedly advantageous to have at hand some figures to express the incidence of fecal *B. coli* in the material under examination. The acquisition of such information would involve certain technical procedures additional to those now prescribed in standard methods for identification of members of the coli-aerogenes group. Furthermore, it would be necessary for standard methods to define what is meant by "fecal" *B. coli*. It is not difficult to identify, on the basis of colony formation, bacteria of the Aerobacter, or aerogenes section of the group. Although attended with more difficulty, it is possible, with experience and practice, to distinguish on eosin-methylene-blue agar colonies of the so-called *B. coli* intermediates.

Bearing in mind that, in taking legal action against interstate shipments, the burden of proof of a charge of filth and potential danger to health rests upon the food law enforcing agency, examination should disclose conclusive evidence of the presence of strains of intestinal origin. The significance of *B. coli* intermediates in this connection will require clarification. In emphasizing the need for differentiation of the coli-aerogenes group, it is not suggested that a score, or other numerical expression based on the group, be abandoned. Such data, considered in connection with inspectional evidence, are informative and should be of value. However, in regulatory control of interstate shipments scores based both on the group and on fecal *B. coli* at present seem desirable.

In the history of the present standard methods, a particularly controversial point has been the question of whether oysters showing a score higher than 50 should be condemned. From the standpoint of interstate control, little need be added to what has already been stated in this paper on this subject if the score is based on the presence of

all members of the coli-aerogenes group.

A procedure commonly followed in the sanitary control of oyster production involves the bacteriological examination of the waters in which oysters are grown. Attention may again be directed to the fact that in interstate control such procedure can be applied only in a very restricted manner, and only in those instances where the food control official may have access to the growing areas. Directions for making such examinations very properly belong in any procedure laid down for the sanitary control of production, but their presence in any set of directions for the bacteriological examination of shellfish would tend to confuse. If the report of the shellfish committee goes so far as to include recommendations for the sanitary control of growing areas, procedures for sea water examinations may quite logically be included. On the other hand, if standard methods are to be drawn up as a guide to the food analyst, methods for the examination of water would seem to have no proper place.

The present standard methods give directions only for the examination of oysters. Clams and other mollusks require attention, and thought must be given to the question of whether an attempt should be made to formulate one method for all shellfish or whether distinctive methods for various shellfish should be devised. Gorham,[4] in his last report as referee on shellfish examination, recommended that a subcommittee be appointed to draw up methods for the examination of clams, mussels, and other shellfish. The anatomy and habits of various mollusks differ sufficiently to make it difficult to formulate one method capable of application to all bivalves. Too little is known regarding the bacteriology of clams in relation to their environment, to predict at this time whether or not it would be possible to include in one method a procedure for the examination of all shellfish.

This paper does not include a discussion of details of technic to be followed in standard methods. Whether the practice of examining only the shell liquor should be abandoned in favor of an examination of oyster meats, or the entire shell contents, and whether the present system of scoring should be abandoned for some other form of numerical expression of results, are matters of laboratory method discussed by others. The purpose of this paper has been to present some comments regarding limitations of usefulness of the present standard methods from the standpoint of interstate control of shellfish, and to make some suggestions as to special lines of study to meet the needs of the food law enforcing officer.

The Psychologic Factors of Health Education*

IAGO GALDSTON, M.D., F.A.P.H.A.
New York Academy of Medicine, New York, N. Y.

IN health education the principal elements are: (1) the educator, animate and inanimate; (2) the thesis and act of education; and (3) the object to be influenced, *i.e.*, educated.

These elements have a variety of other names. Thus, the educator (animate and inanimate) is also termed tools or instruments; the thesis and the act are termed the content and methodology; the object to be influenced, the audience.

In all crafts and arts—and health education may be considered such—effectiveness calls for a knowledge of the nature and competencies of the tools, an appreciation of the character of the design, and an understanding of the quality of the material to be fashioned. As these are fully understood and adapted to each other, so will the end result tend to approximate perfection.

In our craft, that of health education, there is a great deal of simple technology to be mastered. A knowledge of the competencies and nature of our tools, the spoken word, the printed word, the ideogram, and all their modifications, calls for wide excursions into the technics of public speaking, printing, types, paper, layout, color combinations, drafting, etc. In the field of the technologies the notable achievements of the Routzahns are to be signalized. But in addition to the fundamental and all-essential technology, there is also in our craft a large need for psychologic understanding, for our ultimate goal is to influence behavior—dynamically or statically, and the influencing of behavior through the means of persuasion, is essentially a psychologic achievement.

For this reason we must, as we have only lately begun to do, apply ourselves to an understanding of the psychologic implications of the 3 principal elements.

Of the first element, the instruments of education, I will say little if anything. The subject is too large to be epitomized. However, it is essential for effectiveness, to know the nature and competencies of each tool, for, as the wise Goethe said " Who on efficient work is bent—must use the fittest instrument," and it is folly to cut butter with a butcher's saw, or to tickle gristle with a butter knife.

The second element, the thesis and act, commonly designated as the content and methodology, has a very distinct psychologic prerequisite, and to this I have devoted a good deal of consideration.

Let me here give but the briefest of summaries, referring the reader to the

* Read before the Public Health Education Section of the American Public Health Association at the Sixty-fourth Annual Meeting in Milwaukee, Wis., October 8, 1935.

fuller expositions contained in separate papers.*

The methodology of health education, to which content is reciprocally fitted, has the following aims and requires these psychologic observances, namely, we must first arouse curiosity, that is, deflect or direct the stream of consciousness, awareness, and attentiveness of our audience, single or multiple, from the bedflow of its own direction into that which we desire; second, we must enlist sympathy, that is, relate our objective to the egocentricity of our audience, make them (or him) realize the intimate pertinence of the matter dealt with and the goal aimed at; third, we must impart information, *i.e.*, fit into the audience's rational scheme of things—the what and the wherefore of our objectives, thereby incidentally also making an appeal to its emotions by way of intellect, for, be it noted that all men are eager to be considered rational beings.

Fourth and finally, to lead to action, that is, to tie our objectives to the innate emotional motives and psychologic drives of the individual and thus to achieve ultimate realization of our objectives.

These 4 essential psychologic prerequisites are not to be attained in abstraction. They are essences, but they are expressed and they are affected, in quality and degree, by the nature of the instruments employed, by the skill exercised, and most by the qualities of the audience, *i.e.*, of the object to be influenced.

AUDIENCES DIFFER

Audiences differ, and as they differ their psychologic character and susceptibilities differ. Not only do audiences vary in the gross and evident categories of economics, education, and social level, but also according to race, religion, geographic origin, etc. These are obvious differences, fairly widely appreciated. Less so appreciated are the psychologic variations of the same body under different circumstances and in different environments. The mother at home and at a parent-teachers meeting, are two different individuals in whom different psychologic and emotional potentials predominate. So, too, differs the business man when in his office and when fraternizing as "Bill" at the Service Club. The common man is psychologically one mortal in his shop, another in his trade union, club, etc., and still a third in his church.

The psychologic considerations which center about economics, education and social differences of our audiences are essential, but, in themselves, all too limited to accord us an adequate picture.

There are numerous other factors which we must consider.

PRIDE AND PREJUDICE

Each and every type of audience has its singular prejudices.

When the legions of Julius Caesar threatened to revolt, he addressed them as "quirites"—Roman citizens. They objected, we are not "quirites" but "milites," not citizens but soldiers, Roman soldiers. Caesar's rejoinder was in effect "I'd hardly think so by your actions," and the issue was won in no small part by Caesar's knowledge of his soldiers' prejudices.

Again, the facetious story is told of an old Jew on the witness stand, who, when asked his age, suddenly grew deaf and heard not. To all the interpreter's refashioned inquiries, the old Jew replied with an inquiring "Ah?" Then up rose another Jew who knew the old man's superstition, and, with the permission of the court, phrased the inquiry thus: "Rebbe, may you live to be 120, how old are you?" The formula having

* The Psychophysics of Health Education.

possible if each of us were required to wrest its elements from our single lives and experiences. But Euclid having conceived and tried his theorems on the banks of the Nile, has taught all generations to measure the lay of the land. We may not play Euclid in any realms of knowledge, but in most we shall find at least one well informed and eager to enlighten us. If you would know your group, gain insight into its character, learn of its psychologic bias —deal with one of its own who is outstanding in his group, one who is, so to say, a " liaison personage " between your group and his. The priest or minister, the political leader, the journalist (this one a most valuable ally), the doctor, lawyer, educator, and leading business man, the socially prominent woman, these, if you take them into your counsel, will teach you in brief what you could hardly gather in half a lifetime of application.

Above all, bear in mind the similar dissimilarity of mankind. Bread is the staff of life and yet how different the breadstick of the Italian from the pancake loaf of the Armenian. And though each is bread, still will the one be eschewed in preferment to the other—one's own bread. It is for us to be mindful of men's preferments in instruction as in bread.

Toward Prevention of Suicide

SEVEN prominent psychiatrists and three social workers who believe, according to the press, that " the phenomenon of self destruction should be treated as a preventable disease," have formed a committee of research into the motives and impulses that lead to suicide.

A Committee for the Study of Suicides has been incorporated in New York, " to study and conduct research with respect to and to collect, edit, classify, complete and disseminate knowledge, information, data, facts and statistics concerning the history and causes of, motives for and ways and means of prevention of suicides."

The directors of this new committee are:

Elizabeth G. Brockett, social worker, New York

Marshall Field

Dr. Gerald R. Jamieson, psychiatrist, New York

Dr. Herman Nunberg, psychiatrist, New York

Dr. Henry Alsop Riley, professor of neurology and psychology at the College of Physicians and Surgeons, Columbia University

Dr. Dudley D. Shoenfeld, adjunct psychiatrist and chief of the Mental Health Clinic at Mount Sinai Hospital

Dr. Bettina Warburg, formerly of the staff of Bloomingdale Hospital, White Plains

Dr. Gregory Zilboorg, psychiatrist, New York

Dr. Franklin G. Ebaugh, of Denver, director of the division of psychiatric education of The National Committee for Mental Hygiene

Barklie McKee Henry, president of the Association for Improving the Condition of the Poor

The secretary of the committee and director of research is Dr. Gregory Zilboorg of New York.

Water Pollution Abatement in the United States*

H. R. CROHURST

Sanitary Engineer, U. S. Public Health Service, Cincinnati, Ohio

THE report of the President's National Resources Board, December, 1934, provided the basis for a comprehensive long range national policy for the conservation and development of our national resources.

The Water Planning Committee of the Board made the following recommendations relative to water pollution:

> That a permanent water planning section of the National Resources Board, or its successor, be established to assemble promptly the basic data which now exist in scattered places and are needed for planning the use of water.
>
> That it initiate whatever researches are needed for additional data.
>
> That it investigate water pollution in all its phases, including the effect of pollution on fish and other forms of aquatic life and organisms.

The recognized trend of public opinion toward dependence on federal regulation, as a cure-all in water pollution abatement, indicated to the National Resources Board the necessity of assembling promptly, as a criterion for sound future policies, a more dependable inventory of the status of several specific aspects of water pollution than had previously been undertaken.

To obtain this specific information and to carry out the recommendations of the Water Planning Committee, a Special Advisory Committee was appointed December, 1934, to assist the Water Resources Section in making an inventory of the present status of water pollution and control; recommend needed research studies to obtain lacking information; and formulate general future policies for the control of water pollution.†

The writer presents in this paper a review and abstract of the report of the above committee, with which he was associated in its preparation.

The committee assembled its basic information upon which to base its recommendations of future policies in water pollution control:

1. Through correspondence (supplemented in some cases by personal interviews) with responsible officials of all state agencies which it had been able to determine as concerned with administrative control of water pollution, such as state health agencies, conservation commissions, and fish and game commissions.

---

* Read at a Joint Session of the Conference of State Sanitary Engineers and the Public Health Engineering Section of the American Public Health Association at the Sixty-fourth Annual Meeting in Milwaukee, Wis., October 7, 1935.

† The Special Advisory Committee consisted of the following members:
W. B. Bell, Bureau of the Biological Survey, U. S. Department of Agriculture
Lt. Col. Glen E. Edgerton, Office of Chief of Engineers, U. S. Army Engineer Corps
A. C. Fieldner, Bureau of Mines, U. S. Department of the Interior
Elmer Higgins, Bureau of Fisheries, U. S. Department of Commerce
Thorndike Saville, Assoc. Dean, College of Engineering, New York University
R. E. Tarbett, Bureau of the Public Health Service, U. S. Treasury Department
Abel Wolman, Chief Engineer, Maryland State Department of Health

2. Through a Joint Committee of the American Society of Civil Engineers and the American Institute of Chemical Engineers, under the chairmanship of S. T. Powell, with respect to the treatment of industrial wastes.
3. Through Sanitary Engineer H. W. Streeter, U. S. Public Health Service, on the status of standards of water as applied to pollution.
4. Through Dr. M. M. Ellis, Bureau of Fisheries, on water purity standards for the maintenance of aquatic life.
5. Through the State Planning Consultants and the Regional Water Consultants of the National Resources Board.

The report of the Special Advisory Committee presented a summary and digest of the data accumulated from their investigation under the following main divisions:

A. Status of water pollution legislation
B. Status of water pollution from public health aspect
C. Status of water pollution from biological aspects other than public health
D. Status of industrial waste pollution
E. Status of standards of water quality
F. Economic aspects of pollution
G. Recommendations

The committee reached certain general conclusions in respect to water pollution control, which may be briefly summarized as follows:

A. STATUS OF WATER POLLUTION LEGISLATION

Federal legislation—State agencies in general are opposed to any extension of federal regulatory authority with respect to water pollution control. They favor the federal government's confining its activities to investigation and research and to acting as a coördinating agency.

While federal regulatory authority over the control of water pollution is subject to constitutional limitations, it may nevertheless be broadened by Congress.

The interstate compact as a means of dealing legislatively with interstate problems is a relatively little used method of regulating water use. While its limited success hitherto might argue against its employment, the possibilities of the interstate compact as applied to water problems has not been adequately tested. Therefore further consideration must be given to such compacts as an aid to the solution of the problem of pollution administration and control.

The conclusion seems inevitable that, although interstate compacts offer a hopeful means of abating pollution of interstate streams, something more is necessary to make them effective. It appears there is a real desire by state agencies that the federal government should act in guiding and stimulating, and in an advisory capacity. Such action would be in accord with precedent and would promote conditions which would guard against discrimination between local interests and between interests of separate regions.

State legislation—Certain changes in existing state laws are needed if more effective control of pollution is desired. These should include:

a. Adequate administrative control.
b. Delegation to the administrative agency of the power to determine what constitutes that pollution which is prohibited by the statutes, and to establish limits of pollution.
c. Mandatory power to compel installations of works and other necessary action.
d. No limitation on taxing power of municipalities in application to works ordered by the administrative agency.
e. Power to require the provision of facilities through sewerage or sanitary districts or otherwise, to enable municipalities and industries to comply with the law.

B. STATUS OF POLLUTION FROM PUBLIC HEALTH ASPECT

Some progress in the provision of sewerage systems and sewage treatment plants is revealed. The conclusion is also evident that the unsatisfactory progress in sewage treatment is not entirely explained by lack of

legislation, personnel, and funds in the administration of water pollution control.

On the basis of returns which are admittedly incomplete, the following estimates are ventured.

Public sewer systems are estimated to be available to 56 per cent of the total population of the United States; that is, to about 68 million persons. The great majority of the urban population has access to such systems.

The sewage from approximately 28,400,000 persons, about 41 per cent of the urban population, is estimated to receive treatment; that from 14,600,000 persons, 21 per cent of the urban population, is estimated to receive both primary and secondary treatment. This suggests a population of some 40,000,000 persons in urban communities disposing of sewage with no treatment prior to discharge. Not all of this sewage would require treatment, but a considerable portion undoubtedly would.

In most states, present law, administrative personnel and funds are entirely inadequate. In a few states such provisions are excellent. Even in these few more fortunate states, progress toward the abatement of pollution has been unsatisfactory. The basic causes of lack of progress lie in public apathy and in the cost of remedial measures rather than in lack of legislation, personnel, and administrative funds.

C. STATUS OF POLLUTION FROM OTHER THAN PUBLIC HEALTH ASPECTS

A survey of pollution inimical to fish, waterfowl, and other wild life indicates losses of large but indeterminate proportions. The collection of precise data on these intangibles and indirect damages is difficult, as in most states no comprehensive survey has been made. Despite the great interest in sportsmen's organizations, insufficient action has been taken to abate nuisances and abuses, or even to appraise the nature and extent of the effect of pollution on fish and bird life.

In this instance also general public interest is lacking and a sound and thorough educational campaign appears advisable. A complete examination of the entire pollution problem from the point of view of its effects on aquatic life is necessary in order to determine upon the extent of the damage by pollution and upon the expenditures justifiable for its correction

D. STATUS OF INDUSTRIAL WASTE TREATMENT

Each industry presents its own pollution problems, that cannot be solved by general methods of sewage treatment. For many industrial wastes, practical and economical methods of treatment are available. For a limited number, feasible and economical processes of treatment have not yet been developed. In water pollution control, effort should be made toward recovery rather than toward treatment of wastes, wherever practicable. Because of the individual methods of treatment necessary, the prevention of pollution by undesirable industrial wastes demands the active coöperation of industry. That industry has not been entirely inactive in the prevention of water pollution is evidenced by the fact that, in 23 states, there are a total of 523 industrial waste treatment plants of various types, providing varying degrees of treatment for a large number of different classes of industrial wastes. The investment by industry in the prevention of water pollution in these states has been estimated at nearly $25,000,000.

E. STATUS OF QUALITY OF WATER STANDARDS

The use of standards of water quality is limited in this country and is marked by a lack of any general agreement as to what standards, if any, should be

applied to particular kinds of water utilization. With a few exceptions, there seems to be a growing sentiment favoring an effort to devise and adopt, for certain water uses, standards which may be acceptable to those who have to deal administratively with water pollution problems.

From the standpoint of regulation, it is believed that the time has come to determine limiting standards of pollution for at least certain classes of water subject to uses more or less common to the country as a whole. The success with which the application of the Treasury Department drinking water standard has aided in bringing about a general improvement in the quality of public water supplies affords striking evidence on this point.

Before any attempt can be made to formulate standards for general application, there is need for systematic and thorough study. Such studies should be comprehensive in scope and should enlist the services of experts experienced in the various aspects of water pollution and related problems.

F. ECONOMIC ASPECTS

There is an unfortunate, widespread fallacy to the effect that sewage and industrial waste treatment is or can be made self-sustaining or even profitable. The contrary is of course nearer the truth.

The reduction of pollution implies a cost to the taxpayer, measurable in amount. The economic losses to the public due to the failure of treatment, however, have not been evaluated, because very few state officials are willing to venture an estimate thereof. These economic losses are probably large, and tend to offset the cost of water pollution abatement, but at the moment no authoritative figures therefor can be presented.

Taking into account the expressed desire for additional federal coördination and the existence of a multitude of interstate problems, the whole matter of pollution abatement should be viewed in terms of regional social economy on the basis of drainage-basin units.

Inasmuch as substantial advantage would accrue to the national economy by the institution of measures for abatement of pollution, and as a stimulus to local initiative is essential, it seems wise for the federal government to assist in the financing of such enterprises.

RECOMMENDATIONS

On the strength of the data assembled, the special Advisory Committee on Water Pollution is responsible for the following recommendations as a policy for federal participation in water pollution control:

1. That where drainage area authorities exist for the comprehensive development and control of water, their scope be made sufficiently broad to include control of pollution.

2. That no basic changes in existing federal law with reference to water pollution control be made until the experimental program presented later herein shall have indicated whether or not such changes are desirable and feasible.

3. That simplification and coördination of state laws be effected to provide for the following minimum requirements:

a. Adequate administrative control

b. Delegation to the administrative agency of power to determine the nature and extent of pollution prohibited by the statutes, and to establish limitations of pollution

c. Appropriate mandatory powers, particularly the power to compel the installation of essential remedial works and force other necessary action

d. No limitation on the taxing or bonding power of municipalities, when applied to remedial works ordered by the administrative agency

e. Power to require facilities through sewerage districts, sanitary districts, or otherwise, that will enable municipalities and industries to comply with the law

4. That broader authorization for research be granted to those agencies of the federal

government which are already concerned with various phases of the problem, and that adequate funds be provided for properly coördinated water pollution investigations.

5. That powers and funds be granted to an appropriate federal agency to institute a coöperative program of investigation with legally constituted state agencies for such special studies as appear desirable, and particularly for the development of appropriate standards for water use and control.

6. That in order to stimulate the construction of pollution abatement works, funds for the purpose be made available by the federal government to local public and private agencies on a grant-in-aid or loan basis. Lacking any precedent for the designation of appropriate bases for such allocations, the committee recommends the creation of a demonstration unit on a river system selected for that purpose.

Lacking any precedent for the establishment of the bases for such allocations, and for federal coöperation in a program of pollution abatement, the committee recommended the creation of a full-scale demonstration unit on the Potomac River, an interstate stream of some magnitude, involving the mutual interests of four states and the federal government, to demonstrate the possibilities of: (a) better coördinated stream pollution control legislation in the states, (b) more adequate administrative procedures by state agencies, (c) the development of the legal and administrative procedures for regional or metropolitan pollution abatement authorities, (d) the coördination of municipal sewage disposal projects with state-wide or interstate projects, (e) the solution of additional industrial waste treatment problems, (f) the extension of coöperation with industry, (g) the stimulation of public demand for the adequate control of stream pollution.

For the general administrative control of this drainage basin, the committee recommended a board of 5 members, 1 appointed by the National Resources Board and 1 appointed by the governor of each of the four states comprising the drainage basin, with the approval of the National Resources Board. It further recommended that the present Advisory Committee act as the directive agency to consult with and keep informed of the activities of the Administrative Board.

The Administrative Board should be empowered to employ technical personnel; undertake investigations of scientific nature, negotiate contracts with municipalities, counties, states, and private industries; assist in the preparation of plans and specifications for works projects; and develop financial programs for accomplishing the objectives outlined.

The committee estimated the cost of the proposed Potomac River demonstration project at $15,000,000, and submitted detailed estimates of the various items of expense.

Promotion of Certified Milk

A NATIONAL campaign to promote greater use of certified milk by physicians and the general public has been launched by the Certified Milk Producers' Association of America, Inc., with the coöperation of the American Association of Medical Milk Commissions, of which M. J. Rosenau, M.D., is president.

Certified milk is now available in pasteurized form in many of the 1,000 or more communities where this honor milk supply is available.

The campaign in behalf of certified milk is under the general direction of James A. Tobey, Dr.P.H., chairman of the committee on public relations of the association. Literature on certified milk can be obtained from Dr. Tobey at 350 Madison Avenue, New York, N. Y.

POLIOMYELITIS

THE outstanding epidemic in 1934 was an outbreak of poliomyelitis in and around Los Angeles, Calif., of which we gave a full account in our *Journal.*[1] The year 1935 has seen another epidemic, this time in the East, centering in North Carolina and Virginia. In our present issue we give descriptions of this.

During the past year two vaccines against poliomyelitis have been put forward and a number of articles concerning them have been published by the experimenters. Although the Editor has had sources of information which have kept him in fairly close touch with the use of these vaccines, comment has been withheld for reasons which seemed sufficient.

At our Annual Meeting in Milwaukee in October, 1935, a number of papers were presented, discussing the manufacture and use of these vaccines. None of these papers were published, since the Southern Branch of our Association, which met in St. Louis in November, had an extensive symposium on the subject, covering more ground than was covered at Milwaukee, and it was considered best to wait for the latest information available. We are now giving, in addition to the description of the 1935 epidemic, discussions of the two vaccines referred to and one paper read at Milwaukee. All of these papers deserve careful attention, and an editorial notice of them would not seem necessary except to bring out certain points which were not stressed at the meetings.

The first trials of the two vaccines were made without what most of us would consider proper controls. We are publishing a paper[2] given at St. Louis in which the use of a vaccine was carried out under the most careful conditions possible. It is evident that a sufficient number of vaccinations have not been done, nor have there been enough controls to form a definite opinion of either vaccine. The estimates given by Gilliam and Onstott[2] are based on an attack rate of 60 per 100,000 in children under 8 years of age. Supposing that the

vaccine was 100 per cent effective, 10,000 children should have been vaccinated, and 10,000 used as controls in order to reach a fair estimate of its effect. If the vaccine were only 80 per cent effective, it would have been necessary to use 40,000 children, and if older persons were included, it would have been necessary to increase the size of the group tremendously. These estimates are "safely conservative." Others made by competent people have run much higher. It is evident therefore that so far no effectual tests of these vaccines have been made. The number of cases, as well as the number of deaths which have occurred following the use of vaccine, and which are believed by many to have been due to one of the vaccines, are also given. In this connection, Park and Brodie,[3] whose vaccine has been fairly extensively used, particularly in Kern County, Calif., say in their conclusions that at least 50,000 more children must be observed under field conditions in order to reach a positive evaluation of their vaccine, and even this estimate is below some which have been made.

There are two points on which emphasis must be laid, one of which was not discussed at either of the meetings. Dr. Kolmer, in summarizing the cases of poliomyelitis which have followed the use of his vaccine, which he holds were not due to the vaccine, but to the fact that the children were in the stage of incubation when the vaccine was given, has mentioned that in a number of these cases the vaccine was given on one side of the body while the paralysis occurred on the other. In the opinion of competent pathologists, this means nothing, since the paralysis is due to the injury done to the pyramidal cells of the anterior horns of the spinal cord. In virus diseases especially, the effects are apt to appear at a part of the body distant from the point of inoculation.

Dr. Kolmer also repeatedly lays stress on the fact that he used "remote monkey passage virus." While he denies having made a positive statement that passage through the monkey increased the virulence of the virus for monkeys, but decreased it for human beings, he admits that he has put forward such a theory. This has been very thoroughly answered by Flexner,[4] who discusses in the same paper the striking instability of the virus of poliomyelitis.

We call attention to the paper by Dr. Thomas M. Rivers, in which he discusses at some length the virus diseases in general, with particular application of the known facts to poliomyelitis, and from these known facts, deduces his estimate of the value of the two vaccines in use and the dangers of one. Since these papers were written, at least two cases of poliomyelitis have followed the use of the vaccine which Dr. Rivers considered safe but valueless.

In April, 1935, the Director of Health of San Francisco City and County appointed an Advisory Committee to study poliomyelitis and the vaccines, in view of the presence of the disease in California, and the possibility of its reaching San Francisco. The report recommended that the Director of Public Health take no active stand favoring the use of vaccine until its value had been more fully demonstrated, and advised further that the experimental administration be restricted to properly qualified research institutions. The committee also expressed its doubt of the harmlessness of preparations containing living virus. We cannot but think that events since that time have proved the wisdom of the recommendations. On December 27, 1935, the Director issued an Executive Order calling attention to the soundness of the recommendations and prohibiting the use of "such vaccines or other similar immunizing agents" in the City and County of San Francisco.

The immediate cause of this order was a special article by Leake[5] giving 12

cases of poliomyelitis which followed the use of vaccines, with 6 deaths. This article lays stress on a point which is mentioned particularly by Rivers; namely, that the appearance of neutralizing antibodies in the blood after the injection of the virus of poliomyelitis is not positive evidence of an immunity to the natural disease.

We believe that the symposium contained in this issue is the most complete discussion of poliomyelitis as it exists in the United States which has been published. There are many other points to which attention might be called, but we ask our readers to study the articles instead of depending on an analysis, even if it were more extensive and perfect than is here given.

We believe thoroughly in experimental work, and nothing said here should be interpreted as a warning against the study of vaccines for the prevention of poliomyelitis. We all hope sincerely that these and other studies may lead to the discovery of a vaccine against this dreaded disease, but we deprecate the style of advertisement which has been given to these vaccines, particularly in the lay press. Dr. John F. Landon has called attention to the damage being done and asked that some authoritative body, such as the New York Academy of Medicine, sponsor a statement prepared for the public as to the status of vaccines against the disease. We commend this idea to the attention of health officers and medical men generally, and again urge our readers to study carefully the material on the subject given in this issue.

NOTE: The Park and Brodie vaccine has been withdrawn from use on human beings at the request of the directors of the Warm Springs Foundation in Georgia. It is understood that the Foundation has been supplying funds for research in the development of the vaccine.

A BETTER DRUG ACT OR ONLY THE OLD ONE?

S-5 IN THE MAKING

MEDICAL and health and consumer interests hailed the original Tugwell-Copeland Bill in 1933 as expressing a courageous stand of the Roosevelt Administration against the most widespread and lucrative abuses of present-day free commerce in drugs among the people of the United States.

Today after the persistent and successful attacks upon its purpose, integrity of expression, and verbal form, S-5 is as nearly futile and innocuous as the most resourceful drug manufacturer, advertiser, and salesman could desire.

Either the Bill as passed by the Senate at the last session, and now in the hands of the House Committee on Interstate and Foreign Commerce, should be altered to provide some tangible improvement in the drug and cosmetic trade for the safeguarding of the average consumer's health, or it ought to be voted down as unworthy.

Before agreeing to the latter confession of failure, of abject capitulation to the commercial promoters and advertisers who see in medicaments only objects of exploitation for cash profits, we believe five separate and distinct changes in the present text of the bill should be urged upon the appropriate Congressmen by the state and local health officers, and by representatives of all nonofficial health agencies throughout the nation.

The five indispensable changes are the following:

1. Omit the phrase on page 2, lines 10 and 21, "and not for the regulation of the legalized practice of the healing art." Chapter II, Section 201, b and c. This sly little phrase would permit a multitude of abuses by "shyster" practitioners who could carry on an extensive business in the sale of adulterated and misbranded drugs and devices under the guise of professional practice.

2. Delete the sentence beginning on page 13, line 21, authorizing variations from Pharmacopoeial standards, which makes the new bill in this respect practically identical with the present act, and replace it by much more stringent requirements.

3. Section 601 (False Advertisement), page 21, now under attack and likely to be weakened, or its enforcement assigned to the Federal Trade Commission, should be preserved or made more effective, and its enforcement definitely established under the Food and Drug Administration of the Department of Agriculture.

4. Under Section 711a, page 36, the proviso, lines 10–18, should be stricken out as it weakens the seizure provision of the present law and would unduly hamper the government in proper seizure on evidence of misbranding. In matters of this kind where the public health is at stake or where flagrant deception of consumers exists, no restriction should be placed on the exercise of seizure to remove offending goods from the market before they reach consumers and do their damage.

5. Under the same Section 711a, on page 36, the provision, lines 18–20, "That said single seizure action shall on motion, be removed for trial to the jurisdiction of the claimant's residence," should be deleted so that, as under the present law, the action will be tried where the seizure is made—that is, in the consuming rather than the manufacturing jurisdiction. For the same reason a similar change should be made in paragraph (b) of this same section by striking out the words on page 37, lines 6 and 7, "or for the district of the claimant's residence."

There is some merit in the Bill as it now reads but hardly enough to justify any support by health, or medical, or consumer interests.

With the changes suggested it could become a powerful weapon of offense or defense for the welfare of the public.

AMERICAN CHILD HEALTH ASSOCIATION COPYRIGHTS TO THE AMERICAN PUBLIC HEALTH ASSOCIATION

IN the advertising pages of this *Journal* a list of publications appears which were prepared and formerly distributed under the aegis of the American Child Health Association.

The Executive Board of the American Public Health Association has acknowledged this gift with appreciation and has approved the transfer of 15 copyrights in the name of the American Child Health Association. The publications these

documents cover are now the property of this organization. These, together with certain instruments of measurement developed by experts of the American Child Health Association and additional books and pamphlets, the copyrights of which are still owned by the original recorder, are now available through the Book Service.

By keeping alive and current these valuable aspects of the work of the now dissolved American Child Health Association, we shall hope to continue the service so competently rendered to the public health profession by that agency in the past.

ANNA M. PABST

RESEARCH has claimed another victim. The Public Health Service has recorded on its special honor roll Anna M. Pabst, who died of meningitis on Christmas night in Washington, D. C. Miss Pabst was working on meningitis serum. While injecting an animal on December 17 at the National Institute of Health, it moved and some of the culture was squirted into her eye. In spite of prompt cleansing she was stricken on December 21 and died on December 25. She was very highly regarded at the National Institute of Health.

Those who use biological products, which have done so much to take away the dread of many diseases, do not realize the risks that laboratory workers run in their study. Science has an entirely too long roll of honor brought about by accidental infection in studying disease. This *Journal* and the Association which it represents unite with others everywhere to honor this latest martyr to science.

THE OPEN FORUM

REGINALD M. ATWATER, M.D.
Executive Secretary, American Public Health Association

DO YOU USE THE EMPLOYMENT SERVICE?

ATTENTION is called to the fact that the Association has for years maintained an exchange between employers and employees in the field of public health.

In 1936 it is planned to expand and improve this service with special reference to the demands which may be made upon the Association as a result of the application of the Federal Social Security Act. A systematic recording of all persons trained and experienced in technical public health activities is being compiled for the benefit of agencies of the United States Government and of the state departments of health.

Persons desiring to register in this connection should write to the office of the Executive Secretary for the appropriate blanks. No charge is made for the service of the Association or for publishing announcements of applicants who are members or Fellows.

The attention of prospective employers is directed to the fact that announcement of examinations through civil service channels or otherwise will be carried in the *Journal* without charge and that they are welcome to consult the Association on matters of employment. It is the policy of the American Public Health Association to assist employers and employees, properly qualified, to get together. It is not the policy of the Association to recommend employees for particular positions.

END OF YEAR PUBLICITY

I HAVE been interested to see this year how many good health officers are taking advantage of the timely interest of the public in the records for 1935 by having a summary of health department results ready for publication promptly after the close of the year. Some of the department are evidently closing their books a bit before December 31, in order to take advantage of the psychology that comes with new year time.

Among the releases which were ready this year, I was struck by that of Baltimore's City Health Department in which the outstanding problems of the city are thoughtfully presented by Dr. Williams and Dr. Fales. Syphilis is presented as an outstanding enemy of health, and it interested me to follow through to see how much newspaper coverage a statement of this sort received.

This statement has appeared in conservative papers throughout the city, and " syphilis " has been repeated more frequently than is customary because of the emphatic way in which the facts are presented. The matter is covered editorially very well and, in addition, there is a comment by one of the regular columnists which rather effectively brings the attention of the public to the health department.

Most outstanding, however, is a Christmas Eve editorial in one of the papers which, under the title of " Glad

Tidings," recommends attention to the report because of its good news on the control of diphtheria, and goes on to say that, if only the shame and secrecy with which syphilis is surrounded could be overcome, it would be possible to rid society of this menace as well in a generation.

We have waited a long while for the papers to turn about face on their attitude on syphilis publicity, but this time seems to have arrived in Baltimore.

THE CENTURY MARK IN LIFE MEMBERSHIPS

IT is a pleasure to record that the number of Life Members in the Association has reached and passed the hundred mark with the beginning of 1936.

One hundred and five of our members who believe in the Association and who know their own minds on their professional careers have chosen this means of relieving themselves of all future worry about dues. And they have in the aggregate saved money, too. Have you considered this opportunity at the beginning of 1936? "It's smart to be thrifty."

DO WE HAVE CLEAR THINKING STUDENTS TODAY?

DR. Thomas Parran, Jr., in his Biggs Memorial Lecture, given on May 2, 1935, quoted from the graduation thesis 54 years ago of Dr. Hermann M. Biggs, who was a candidate for the bachelor's degree in Cornell University. The subject of the thesis was "Sanitary Regulations and the Duty of the State in Regard to Public Hygiene."

These abstracts from Dr. Biggs's thesis are so revealing and shed so much light on the insight which Biggs had half a century ago that they are reproduced here. I believe they should be made a matter of record more widely available.

> This is a period in our national history in which sanitary science is receiving a large and constantly increasing share of public and professional attention. The last half century . . . has been marked by great advances made in this direction; advances which we may reasonably believe are but first indications of the greater developments in the future.
>
> The enjoyment of health, immunity from suffering, and long life, are the greatest temporal blessings that man can desire. . . . There are certain natural and sanitary laws that regulate the functions of life, . . . insure a more uninterrupted enjoyment of health, exemption from many infirmities, and a prolonged existence.
>
> Upon the recognition and careful observation of hygiene laws depend the healthy physical condition, and so the prosperity not only of individuals and communities but also of whole states and nations. . . .
>
> . . . There are other considerations far higher than the financial one which render governmental action in regard to the public health imperative. . . . Not only is the physical condition of a public dependent upon their sanitary surroundings but their moral and intellectual condition is also largely determined by those same surroundings.

Through several sessions of the Legislature from 1919 until his death, Biggs fought for an integrated system of preventive and curative medical service in the state. He proposed:

> 1. To provide for the residents of rural districts, for industrial workers, and all others in need of such service, scientific, medical, and surgical treatment, hospital and dispensary facilities, and nursing care at a cost within their means, or, if necessary, free.
>
> 2. To assist the local medical practitioner by providing facilities for accurate diagnosis . . . both hospital and out-patient; consultation and advice as to treatment by medical and surgical experts; clinical, pathological and chemical laboratory service and X-ray facilities, at a moderate cost or free when necessary.
>
> 3. . . . Facilities for an annual medical examination . . .
>
> 4. . . . Adequate school medical inspection and school nursing service.
>
> 5. . . . Better . . . administration of public health activities . . .

6. A public health nursing service adapted to and adequate for the community served.
7. . . . Dissemination of information in regard to public health . . .
8. Adequate compensation for medical and surgical service rendered in hospitals and clinics . . .
9. Laboratories, diagnosticians, consultants, and hospital facilities in the smaller cities and rural districts.
10. Medical libraries and health educational material.
11. Hospital and other necessary resources for dealing promptly with epidemics.
12. . . . Prompt and accurate diagnosis and surgical treatment for sick and indigent (industrial) workers and members of their families.
13. Coördination of public health activities within the districts.

WILL YOU BE IN ENGLAND THIS SUMMER?

THE Royal Sanitary Institute will meet again in Southport, England, July 6 to 11, 1936. At its meeting on December 19, the Executive Board authorized the Executive Secretary to appoint members of the Association who might be in England during the days of this health congress to represent the Association. The Executive Secretary will be very happy to have word from any members or Fellows who plan to be in England at that time.

"THE CONTROL OF COMMUNICABLE DISEASES"

THIS new publication which was announced at the Milwaukee meeting has already gone through a large edition and is being reprinted. Orders have been received from all sorts of official and private agencies. One state health department is considering an edition of 2,000 copies with its own imprint, as the document has been made official. It carries also the approval of the Surgeon-General of the U. S. Public Health Service. Have you your copy? Is your staff completely supplied? It is doubtful if there is any other publication at the price of this edition which answers so many questions in so authoritative a way.

FOR YOUR LITERATURE TABLE

A BOOKLET entitled, "Your Friend, the Health Officer," written by Dr. Wilson G. Smillie of Harvard, has recently come to my attention, a publication of the Life Conservation Service of the John Hancock Life Insurance Company, of Boston. This is a very readable story about the health officer's function which might be of utility in many places where the public service rendered by the health officer is still regarded as a mysterious occupation, easily to be dispensed with.

A MANUAL FOR TEACHERS

AN unusually attractive document has come to my desk from Madera County, Calif., of which Dr. Lee Alexander Stone is the full-time Health Officer. This publication, which is called "Principles of Good Public Health Practice," is a manual for use by the principals and teachers of the schools in Madera County. It is a mimeographed publication of about 100 pages, made unusually attractive through various typographical means. It answers a thousand questions of the school teacher on health subjects. Although claiming no originality in the publication, there is reflected something of a different quality from many publications of this sort and, if a county of 18,000 persons with limited financial resources can produce as creditable a manual as this, it ought to be equalled by a good many larger units.

TOXOID ITEM

THE Dionne Quintuplets have each received three doses of diphtheria toxoid from Dr. Dafoe and Dr. A. L. McKay of the Ontario Department of Health. This fact should encourage

many a parent to do likewise if health departments will utilize this news.

A CORRECTION

THE chart illustrating the usual course of measles carried in this column last May (page 641; also page 1354) which was credited to the Michigan State Department of Health should have been credited to the originator, Dr. Charles F. McKhann of Boston.

ARE YOU "CAUGHT UP"?

DO you ever get caught up on public health education? If you do, this story relayed by a friend in West Virginia will certainly have an appeal. He tells of a neighbor of his, a Portuguese farmer, to whom he offered a book on crop rotation and soil rejuvenation. The farmer refused it, saying: "I don't farm as good as I know now." How many people do not live "as good as they know" now?

PUBLIC HEALTH EDUCATION*

The Quints as Health Educators —Is it not likely that great numbers of people have been reading about the better care of babies who would refuse to look at a health department article in the newspaper? And all because of the gold fish life of 5 little girls!

Today's headlines in one evening paper:

> Quints Display Curiosity, Not Fear, As Doctors Administer Toxoid.
>
> The Quints Make a Game of Diphtheria Injections; Marie Cries, but All Others Gurgle with Glee.

Here is part of the report of the third injection:

> The scientific care which has brought the Dionne quintuplets safely through 19 perilous months has now also provided them with the best known protection against diphtheria.
>
> Despite the nursery precautions against infection and despite the almost perfect health of the babies today, Dr. A. R. Dafoe decided to take no chances with diphtheria. He felt that without special toxoid protection the risk of that deadliest scourge of childhood was too great.
>
> So the 5 little sisters have now successfully completed a course of 3 injections each of anti-diphtheria toxoid. The first treatment was in November and the last just before Christmas.

The N.E.A. Service report then quotes Dr. Dafoe and Dr. J. A. Faulkner, Provincial Minister of Health, who say what health officers have been telling their publics for a number of years. And these quotations have been published widely all over the United States and Canada.

One of Six—At St. Louis, during the meeting of the American Association for the Advancement of Science, a special interview was given by the Association president, Dr. Karl T. Compton, who is president of the Massachusetts Institute of Technology.

Dr. Compton offered a 6-point program for the broad welfare of the nation, one point being as follows:

> Recognize prevention and conquest of physical and mental diseases as far more economical and humanitarian than merely the care and treatment of those already afflicted.

Educate Them All—C. E. Davis discusses "The Rôle of the Hospital in the Education of Doctors, Nurses, and Others Engaged in the Care of the Sick." The "others" include

> The housekeeping personnel, made up of the janitors, window washers, maids, sewing women, laundry workers,

all of whom play an important part in the hospital environment. The author is more insistent upon learning ability being limited to the young than the studies of E. F. Thorndyke would seem to support.

In *Hospitals,* 18 E. Division St., Chicago, Ill. Jan., 1936.

The Hospital in Health Education —Says Ira V. Hiscock, "Mutual Interests of Hospitals and Public Health Organization":

> The hospital and the clinic have a responsibility for the education of both patients and personnel. The opportunities of health education in the clinic have been ably discussed by Galdston, who urges that the clinic, instead of being only a place to which the lame and the halt go for cure, might also serve as a center where persons

---

* Please address questions, samples of printed matter, criticism of anything which appears herein, etc., to Evart G. Routzahn, 130 East 22d St., New York, N. Y.

might be instructed on how to keep well. Our present-day knowledge of the nature of disease indicates that to cure a patient we must also teach him. Preventive medicine, even more than curative, depends for effectiveness upon education. Dr. Lawrason Brown, speaking on the rôle of education in the treatment of tuberculosis, said that he looked upon the sanatorium as a sort of college where men and women were reëducated in a newer method of living. If the tuberculosis patient needs to be reëducated to a newer method of life, many other types of patients, both in the clinics and in the hospitals may likewise be served.

The clinic offers an excellent opportunity for general health education through visual methods and literature, and for special instruction regarding immunization against disease. Through physicians and nurses in maternity and children's hospitals, a unique opportunity for instruction in maternity and child care is provided.

The clinical-pathological conferences in some hospitals, besides special lecture series, are valuable from a public health viewpoint as well as for clinical purposes. High standards of medical and surgical practice favorably influence the public health experience of a community. Stimulus may be given to house physicians to take epidemiological as well as purely clinical histories, and to consider the social backgrounds of their patients in relation to other problems. Such topics as the indications for the use of anti-pneumococci serum and the importance of filling out case records properly are timely. The Connecticut Department of Health makes a valuable contribution to the education of pupil nurses through a course of public health lectures given upon request at nurses' training schools.

In *Hospitals,* American Hospital Association, 18 E. Division St., Chicago, Ill. Jan., 1936.

By Pennies and Half-pennies—The Boston Health Department and other agencies are interested in a new exhibit project described in *Bulletin,* Boston Council of Social Agencies, 43 Tremont St., Boston, Mass. Dec., 1935.

The Health Education Committee of the Boston Health League is much concerned with the question, for many people, of obtaining sufficient food in the face of rising food costs and limited incomes. At a meeting in the early fall, it was decided that a series of food exhibits demonstrating elementary principles of nutrition, if placed in the Health Units, would be seen by large numbers of people and would be a practical method of teaching food values and how to spend food money to help insure good health. The present plan contemplates one new exhibit each month, moving the preceding one to another Health Unit.

Enthusiastic coöperation in working out the plans has been given the committee by the City Health Department, the Department of Public Welfare and the nutrition workers of the voluntary agencies.

The first exhibit depicts the importance of including in the day's meals the whole-grain bread and cereal. Gay yellow streamers lead from loaves of bread, and red bowls containing cereals, to charts that show plainly how the different kinds of bread and cereals compare in their content of iron, while shining new pennies or half-pennies indicate the cost of a single serving. The observer sees that a certain cereal is a little more expensive than another, but also that it contains more iron and should, therefore, be his choice.

The Editorial of the Month—Under "Medicine's Academy" the *New York Times* (Jan. 3, 1936) said:

The arts, letters, and sciences have all their "academies," but nearest to the public is the academy concerned with the health of the people. The president of the New York Academy of Medicine, Dr. Eugene H. Pool, emphasized this relationship in his address last night at the annual meeting, for while the academy seeks directly to keep the profession informed as to advances in medical science . . . its ultimate interest is in the health welfare of all the people of the community—individually and collectively.

To that end it maintains an information bureau for the receipt of inquiries from any quarter. Thousands of these are made in the course of the year and answers given, carrying to home or office the latest and best information that the science has to offer. But it does far more than answer individual and organizational inquiries. It furnishes "releases" to the press on important medical subjects and arranges for radio addresses over the major systems—especially addresses by fellows of the academy which reach practically every part of the country. It also assists public health

organizations in their educational activities. In addition to these, lectures for the lay public are given in the academy's lecture hall.

Every month we would like to reproduce at least a part of a newspaper editorial. Please submit your nominations.

New York City Is Broadcasting—These paragraphs are from the 1934 annual report of the New York Tuberculosis and Health Assn., 386 4th Ave., New York City:

The radio service, which is conducted in coöperation with the Medical Information Bureau of the New York Academy of Medicine and the local county medical societies, reaches vast numbers and makes possible a well rounded health education program throughout the year. So established are the high standards of this coördinated service on the air that the stations look to it for information, not only in connection with the subjects that form the Association's main concern, but also in regard to many other matters pertaining to health.

Last year a total number of 381 radio broadcasts reached audiences listening in on 13 different stations in New York City alone. These stations are exclusive of the nation-wide networks where our programs have been offered by one of the broadcasting companies to its complete network of 100 stations throughout the country. Certain weekly programs have included as many as 150 stations, and during special campaigns, this number increases.

The majority of these broadcasts are given by physicians, fellows of the New York Academy of Medicine, and members of the County Medical Socities, as well as by members of the dental societies and by professional workers representing social and health agencies.

The broadcasts given during the Early Diagnosis Campaign covered various phases of tuberculosis prevention and work in child health. During the Christmas Seal Campaign, talks and special features were planned for which we enlisted the services of outstanding public health authorities and well known radio personalities. Other related health subjects were covered as season and occasion warranted.

Radio in Canada — "Common Colds," by Gilliam David, is a radio play written for the Health League of Canada. After 10 years of broadcasting health talks by the Canadian Social Hygiene Council a committee was called in the summer of 1935 to study radio education.

The suggestion was made that instead of the regular talk of 12 to 15 minutes, which had previously been used, an attempt be made to dramatize these talks and produce interesting plays and dialogue which would contain much helpful information and at the same time provide a good radio entertainment.

Therefore it was decided that an attempt to produce such plays be made. The committee now announces that a series of 6 such dramas and plays have been written and transcribed electrically for use by radio stations. It is hoped that the series will consist of 24 plays and dramas dealing with such subjects as Common Cold, High Blood Pressure, Anemia, Diphtheria, Preventive Medicine, The Work of the Health Officer, etc.

The manuscript of the plays has been written by Miss Gilliam David. A suitable cast has been chosen and rehearsals have been carried out faithfully until suitable discs have been produced.

Stations located in many parts of the Dominion have agreed to make use of the transcriptions.

In *Health,* 105 Bond St., Toronto, Ottawa. Dec., 1935. *15 cents.*

How to Get Good Housing—This is a sub-heading in "Health and Housing," by Dr. R. St. J. Macdonald in *National Health Review,* Ottawa. Oct., 1935. No subscription price.

The three elements necessary "in order of importance," as outlined by Dr. Macdonald, are education of the public in house hygiene, legislation, and law enforcement.

The people must be told what bad housing means, its evil effects upon their own and their children's health, and how the menace may be averted. They should also have explained to them the essential requirements of a healthy home, so that they may be able to secure one when renting or building.

This education must be extended to all the people, not alone to the housewives who generally do the renting, but also to legislators, architects, builders, land-owners, surveyors, engineers, landscape artists, etc. In addition, janitors, guardians or custodians of dwelling-houses should be given courses in their management.

While, primarily, builders erect houses to make money out of them, yet it must be realized that they may sometimes put up unhealthy dwellings because of ignorance of housing evils, or because they know how frequently housing laws are not enforced.

The people must be educated in personal hygiene. They must be shown the manner in which communicable diseases spread. They must be told that room overcrowding is dangerous; that if a well person sleeps with a coughing case of tuberculosis, there is great danger of the former's contracting the dread disease. It must be explained that a tuberculous person occupying a separate, well lighted and well ventilated room is not dangerous to others if proper precautions be taken. It must be stressed that children cannot grow into healthy, useful citizens if they are brought up in dark rooms; that, like cellar plants, they will be pale and frail weaklings.

Then follow paragraphs about the part of teachers, visiting nurses, general practitioners, the press, public health workers, and social workers.

Ammunition for the job of education is supplied in "America Becomes Housing Conscious," by J. E. Davies, in *Journal of N.E.A.*, 1201 16th St., N.W., Washington, D. C. Dec., 1935. *25 cents.*

Some of the sub-headings will indicate the interesting nature of the material:

Is this a high standard of living? . . . Where children and flowers cannot thrive. . . . Slums—the most costly housing. . . . Cities that don't just grow. . . . Houses at the store. . . . Teaching housing in the schools.

Bulletins or House Organs—Once a year it seems worth while to review the high lights of the contents of the numerous periodicals issued by departments and associations. Unfortunately we are limited to those publications which are received by the editor.

The tuberculosis issue of *The Commonhealth* carries 19 articles. Massachusetts Dept. of Health, Boston. Jan.-Mar., 1935.

The *Red Cross Courier*, Aug., 1935, has a page on "The War Against Pellagra"—from 1735 to Red Cross activities in 1935.

"With the Wisconsin Editors," a section of *State Board of Health Bulletin*, Madison, Wis., reproduces editorials on public health topics.

"A Sanmag Scrutiny," by Elizabeth Cole, and "The Hardest Year" (the first), by J. E. Windram. Not to be missed by those concerned with publications in sanatoria. *Journal of the Outdoor Life*, 50 W. 50th St., New York, N. Y. Dec., 1935. *15 cents.*

More notes next month.

Let's Talk It Over—We have made but a hopeful beginning in the "talking it over" approach to interest and understanding as to public health. "Good References on Discussion Meetings, Open Forums, Panels, and Conferences," by M. R. McCabe. *Bibliography No. 30* issued by Office of Education, Washington, D. C. A 9 page pamphlet listing articles, pamphlets, and books, some of which are sure to be available or easy to secure. *Free.*

Public Health at State Fairs—State departments becoming interested in making use of space at state fairs may wish to consult the state departments of Ohio, Illinois, and New York, which had extensive displays last summer or fall.

State Health Education Workers—Again we have the annual directory of State and Insular Health Authorities, in *Public Health Reports*, Washington, D. C. Dec. 20, 1935.

The following health education titles are listed:

Connecticut: Bureau of public-health instruction
Illinois: Division of public-health instruction
Indiana: Bureau of health education
Iowa: Division of child health and health education
Kansas: Division of public health education
Kentucky: Bureau of public health education
Maryland: Committee on public health education
Michigan: Bureau of education (director, assistant director, lecturer)
New Jersey: Bureau of public-health education
New York: Division of public-health education
Ohio: Bureau of publicity
Pennsylvania: Division of public health education
Texas: Bureau of public health education
West Virginia: Bureau of public health education
Wisconsin: Bureau of education

As may be noted four states are "public-health," while six are "public health."

Only one state lists more than a single person in the bureau or division.

Hygeia, January, 1936—Published at 535 N. Dearborn St., Chicago, Ill.

Does illness begin at forty? . . . Curious stories about health. . . . The 1936 models in diet. . . . Pocket calorie index (illustrated chart). . . . The riddle of the blood relation (a medical mystery). . . . Which is the weaker sex? . . . Health gadgets for the gullible. . . . Toys and games that teach and train. . . . P.A.D.—Prevent asphyxial death. . . . Glands—their influence on body build and behavior. . . . Edward Jenner. . . . Rickets. . . . Mouth reconstruction. . . . What is a mastoid? . . . Venereal disease—the modern plague. . . . Puberty in fact and fancy. . . . Budgeting the reserve strength of the heart. . . . New traveler's clothing. . . . The lens maker (a play). . . . New health books. . . . Questions and answers.

In "School and Health" section:

When a child is mentally healthy? . . . Health teaching in January. . . . A classroom demonstration in nutrition. . . . A health play brings interesting and effective results. . . . New health books for teachers and pupils.

DATES AHEAD

February 9—Incorporation of American Social Hygiene Assn. in 1914. An anniversary significant in the social hygiene movement.

February 10—The first hospital in the modern sense of the word, the Pennsylvania Hospital, opened its doors to patients in 1752.

February 22—Washington's Birthday. An opportunity for contrasting health conditions and the care of the sick of Washington's time with what prevail today.

March—The first visiting nurse started her rounds to the sick poor in March, 1877, although an untrained woman visited disabled sailors and soldiers in Charleston, S. C., in 1813.

Additional information about the above and future dates will be found in "News Almanac for Social Work" for 1936. Community Chests and Councils, Inc., 155 E. 44th St., New York, N. Y. *50 cents.*

A first use for such dates may be in staff meetings and in staff house organs, with possibilities for wide utilization in the newspapers, by radio, in meetings, etc.

FOR REFERENCE OR EDUCATION

"Competitive Plagues of Mankind," by D. B. Armstrong, M.D. Reprint. Metropolitan Life Insurance Co., 1 Madison Ave., New York, N. Y. Heart disease, cancer, pneumonia, accidents, tuberculosis.

"Don't Spare the Soap!" by Shirley Wynne, M.D. Reprint. Free, from Health Cleanliness Service of Procter and Gamble, 80 E. 11th St., New York, N. Y.

"The Economic and Social Aspects of Socialized Medicine," by Iago Galdston, M.D. Reprint. Address the

author, 2 E. 103d St., New York, N. Y.

Four page folders; limited, well written text; plenty of white space; from New York City Department of Health: "For Expectant Mothers," "Gonorrhea," "Syphilis."

"Growth of School Leisure Time," and "School Health Problems Through the Years: Boston Public Schools 1635–1935," by J. P. Sullivan, supervisor of health education, Boston School Department, Boston, Mass. Reprints. Address the author.

"Health Facts," a "scrap book" of selections for use in writing about public health. Grouped under "Health Can Be Measured," "Health Can Be Purchased," "What Tax-supported Health Agencies Do," and "What Voluntary Health Agencies Do." 24 pages. *20 cents.* National Health Council, 50 W. 50th St., New York, N. Y.

The latest addition to the group of aids for those concerned with housing is *Housing Digest,* a mimeographed bulletin issued by Housing Division, Public Works Administration, Washington, D. C. This is "an abstract and index of current thought on housing problems, foreign and domestic." Intended primarily for a busy staff it is likely that copies will be sent upon request from a public health worker.

Most of the publications of the former American Child Health Association will be handled by the American Public Health Association and by the National Education Association, 1201 16th St., Washington, D. C. Those handled by the A.P.H.A. are listed on pages XIV and XV of the advertising section of this issue.

"National Aspects of the Social Security Program as They Pertain to the Children's Bureau," by Katharine F. Lenroot. Reprint. Children's Bureau, Washington, D. C.

The November releases of Health News Service, 22 E. 40th St., New York, N. Y., covered mouth hygiene subjects. Child hygiene was presented in January. This material is supplied free for newspaper use. A new service illustrates the answers to health questions. The style is that of the familiar "Believe It Or Not." Be sure to get samples. May be used in different ways.

"The Pro and Con of Vitamin D Milk," by F. O. Tonney, M.D. Reprint. Address the author: 6737 Greenview Ave., Chicago, Ill.

"Public Health Service Milk Ordinance and Code: 1935," is a fully indexed pamphlet with halftone and linecut illustrations. Superintendent of Documents, Washington, D. C. *15 cents.*

The recent annual meeting of National Society for the Prevention of Blindness, 50 W. 50th St., New York, N. Y., included a session on "The Problem of Fireworks Accidents." Four of the addresses are available in mimeographed form.

"What Is the Early Case?" In *Tuberculosis Abstracts.* Dec., 1935. Free from a tuberculosis association.

GRAPHIC MATERIAL

Hygiene museum interest in different sections of the country was reported to the Governing Council by the Committee on American Museum of Hygiene of which Dr. Victor C. Heiser is chairman. The report will appear in the annual *Year Book* of the A.P.H.A.

"Puppetry Bulletin," for 1935–1936 is obtainable of Paul McPharlin, Birmingham, Mich. Enclose *3 cents* postage. Almost indispensable if you are interested in puppets or marionettes, with its addresses for supplies and equipment, mention of late books and pamphlets, and other current information.

"On Relief" is one of the best examples of American produced Dr. Neurath type of graphic presentation.

Prepared by Graphic Unit of the Research Section, Federal Emergency Relief Administration, Washington, D. C. There are 21 good sized charts, in two colors, with an explanatory statement of 50 to 125 words on the opposite page. Probably copies will be supplied by addressing Washington, or the director of the Graphic Unit, Rudolph Unit, Pictorial Statistics, 160 E. 36th St., New York, N. Y.

MAGAZINE ARTICLES

" Birth-control Debate Renewed." " Question, once furtive, now discussed in public hearings." *Literary Digest,* New York City. Dec. 14, 1935. *10 cents.*

" Colds and Where to Catch Them," by F. S. Bigelow. *Saturday Evening Post,* Philadelphia, Pa. Nov. 30, 1935.

" Give Your Brain a Chance," by Dr. C. W. Sawyer. " Science and common sense have taken much of the mystery from insanity." *Rotarian,* 35 E. Wacker Drive, Chicago, Ill. Jan., 1936. *25 cents.*

" The Robinsons' Dog Has Rabies," by S. J. Crumbine. *National Parent-Teacher Magazine,* 1201 16th St., Washington, D. C. Jan., 1936. *15 cents.* " The Robinsons took a chance in not taking it more seriously when their pet began to act queerly."

" Someone Must Pay," by J. Frampton. " Home Safety " (editorial). *Kiwanis Magazine,* 520 N. Michigan Ave., Chicago, Ill. Dec., 1935. *15 cents.*

" That New Baby," by Dr. W. R. Ramsey. *Farmer's Wife,* St. Paul, Minn. Dec., 1935.

" The Truth About Colds," by J. W. Ephraim. *American Mercury,* 570 Lexington Ave., New York City. Jan., 1936. *50 cents.*

MOTION PICTURES

" Adapting Animation " and " New Wrinkles on Newsreels " are two articles for the amateurs who wish to make fuller use of the technic available. *Movie Makers.* Amateur Cinema League, 105 W. 40th St., New York, N. Y. Jan., 1936. *25 cents.*

" Films for Theatres, Clubs, Schools and Other Organizations." A new descriptive list of movies and film strips offered by Metropolitan Life Insurance Co., 1 Madison Ave., New York, N. Y.

From American Social Hygiene Assn., 50 W. 50th St., New York, N. Y., comes this announcement:

> Three-reel talking film, Science and Modern Medicine, prepared by a special committee of the association to accompany the drama, Damaged Lives, may now be had for non-commercial showings separately from the drama. The film deals with the process of human reproduction and with the so-called venereal diseases—syphilis and gonorrhea—and their effects on individual health and family life.
>
> Both 35mm and 16mm are sold or rented.
>
> Ask for free booklet, A Three Point Program in Health Education, Pub. No. 852, which gives scenario and text, and outlines of the Special Series of pamphlets prepared by Dr. William F. Snow, Health for Man and Boy, Women and Their Health and Marriage and Parenthood, which are recommended to supplement this film. These may be secured for *15 cents* per set.

NEW

Hospitals, to succeed *Bulletin,* American Hospital Assn., 18 E. Division St., Chicago, Ill. An extensive professional journal, 11½ by 8½ inches, 136 pages. No subscription price given.

RADIO

The Department of Health, New York City, is now broadcasting according to the following schedule:

Monday, 2:45 p.m., WNYC
Tuesday, 2:15 p.m., WVFW
Wednesday, 10:45 a.m., WARD
Wednesday, 12:00 p.m., WNYC
Wednesday, 4:30 p.m., WBNX
Thursday, 3:30 p.m., WRAD
Friday, 9:45 a.m., WINS

Recent broadcasts by several state and city departments are listed below.

Baltimore City Health Dept. (auspices of Medical and Chirurgical Faculty of Maryland):

Our city's health and the Community Fund. . . . Crippled hearing. . . . Children who eat paint. . . . Some common dangers in the home. . . . The relationship between the City Health Department and the Department of Public Welfare. . . . Tuberculosis is everybody's business. . . . Why little Mary won't eat. . . . Preventive dentistry. . . . Tularemia. . . . Santa and good health. . . . Dr. Kelly speaks on radium and X-ray. . . . Common sense at Christmas time. . . . Taking Lord Baltimore's pulse (health survey).

Connecticut State Department of Health (by different staff members):

Keep your garage doors open. . . . Mental hygiene makes progress in Connecticut. . . . The septic tank. . . . Making ice cream a safe food. . . . Guarding the health of future generations. . . . The public health nurse's place in the community health program. . . . Emotions under control. . . . The state of our health.

Illinois State Dept. of Public Health (given by Dr. C. W. Chamberlain, Division of Communicable Diseases):

Over-weight and disease resistance. . . . Wars and rumors of wars (wounds and disease). . . . A soldier of fortune (Louis J. Cantor). . . . Newer knowledge of disease resistance and physical differences in mankind. . . . They call them accidents (in the home). . . . The new doctor diathermy. . . . Highway hysteria. . . . Privileges and perversities of the poor pedestrian. . . . A health officer looks at Ethiopia. . . . Can the newer generation face the facts? . . . Is this the most common disease in America? (sinus trouble). . . . Physical activity and disease resistance. . . . The big bad wolf—superstition. . . . You don't believe in doctors? . . . Babies, burns, blisters, and brews. . . . Lending nature a helping hand. . . . Hear ye! Hear ye! (hearing). . . . More martyrs in medicine. . . . Newer approach to speech defects.

Ohio State Department of Health:

Tuberculosis control and the school child. . . . Maternal and child hygiene program under the Social Security Act. . . . Carbon-monoxide poisoning. . . . The school nurse. . . . Just teeth. . . . What have you on deposit in your heart bank? . . . Epidemic meningitis. . . . Diphtheria.

CHILDREN AND SCHOOLS

"A Project in Rural School Health Education," by Ruth E. Grout. Reprint from *Milbank Memorial Fund Quarterly Bulletin.* Includes "Initiating the Study," "Building the Program," "Unit Teaching," "Relationships With Community Health Programs," and "Home-School Relationships."

"The School Doctor States His Case (the school, the home, and the community share responsibility for the protection of child health)," by Harold H. Mitchell, M.D. "Turning the Light on School Lighting," by Hugh G. Rowell, M.D. *National Parent-Teacher Magazine,* 1201 16th St., N. W., Washington, D. C. Dec., 1935. *15 cents.*

Health Bulletin for Teachers, School Health Bureau, Metropolitan Life Insurance Co., New York, N. Y. The 1935–1936 issues will be devoted to "the Conquest of Disease," the primary aim being

To tell in simple and dramatic form the story of the conquest of certain typical plagues of mankind. The affections have been selected to illustrate various types of disease (communicable, constitutional, dietary, mental) and to illustrate the biological, geographical, and socio-economic factors contributing to their control. Practical applications and limitations of present knowledge will be appropriately emphasized.

BOOKS AND REPORTS

The Pneumonokonioses (Silicosis): Literature and Laws of 1934 —*By G. G. Davis, E. M. Salmonsen, and J. L. Earlywine. Chicago: Chicago Medical Press,* 1935. 490 pp. Price, $10.00.

The present compilation of references on one of the most important occupational diseases—silicosis—is the second volume of a series. The first volume contained a bibliography of nearly 3,000 references dating from 1556 to 1933, inclusive. The present volume, including all the publications on the subject issued during the year 1934, has the added advantage of presenting a brief abstract of each article. The book is made up of two parts, the Abstracts and the Laws: the Abstracts are followed by an Authors' Index and a Subject Index. In addition, certain references omitted in Book I are included in this new edition.

In the reviewer's opinion, many of the newspaper accounts included in the book could very well have been left out, thereby giving a more scientific aspect to the volume. Personally, the reviewer would rather that the references were arranged according to subject matter instead of the alphabetical treatment presented. Thus, a reader who is interested only in the pathology of asbestos dust inhalation would find all the articles on this subject listed in one place.

These suggestions are offered for consideration should additional volumes on this subject be in progress, and are not meant to detract in any manner from the value of this book to students of dust inhalation. Indeed, the authors are to be congratulated for their courage and perseverance in undertaking the difficult task of compiling the two books issued to date. Both volumes should prove to be extremely useful to students of this occupational disease.

R. R. SAYERS

Industrial Medicine—*By W. Irving Clark and Philip Drinker. New York: National Medical Book Co.,* 1935. 262 pp. Price, $3.00.

This book which is one of a series of monographs, proposes to clarify the knowledge of the general practitioner in regard to what industrial medicine is and to inform him of standard practice in this field.

The first part of the book is disappointing in that it does not adequately cover its field. It is not broad enough for a text and is too broad for concise expression. We cannot agree with the authors for example, that the limited discussion of fractures, injuries, and sprains has a place in a book of this type, for any surgeon knows more about these conditions than can be learned here. Nor do we believe that physicians in industry will care to share the responsibility of caring for the general practitioner's private patients by doing laboratory and other technical work for him. This can easily constitute interference with the patient's own physician and divided responsibility for any patient is undesirable. The chapters on organization are not comprehensive enough to be of universal value.

That portion of the book which deals with the occupational diseases more than compensates for any faults that may exist elsewhere. The chapters on pneumoconiosis are excellently and clearly written, and describe in an understandable manner an inherent disease of industry about which little

is known by the profession in general.

The concise presentations of other occupational diseases and methods for their prevention make the book valuable for reference. The extensive bibliography is especially valuable in this connection. The book is well indexed but the illustrations are of little consequence except those in the chapters on pneumoconiosis.

We believe it a worth while addition to any medical library.

D. B. LOWE and W. C. ARTHUR

Sanitation and Health Standards for Summer Camps—*By E. B. Buchanan, M.A.; R. J. Ochsner, M.D. Published by the Anti-Tuberculosis League of Cleveland and Cuyahoga County, 1601 Builders' Exchange Building, Cleveland, Ohio.* 55 pp.

This is an excellent mimeographed manual of great practical value. It is based on many years of experience in handling camps and camp sanitation in the Cleveland area.

It covers such items as choice of grounds, toilets, garbage disposal, kitchen sanitation, water supplies, bathing facilities, medical and nursing supervision, and fly and mosquito control.

Including, as it does, definite directions and sketches for the construction of camp sanitation facilities, it is a valuable practical treatise for those responsible for good health in camps. Any camp director would do well to have and study it.

CHARLES H. KEENE

Socialization of Medicine. *The Reference Shelf, Vol. 10, No. 5. Compiled by Julia E. Johnsen. New York: H. W. Wilson Company,* 1935. 335 pp. Price, $.90.

We may expect a number of books such as this on the general subject which it discusses. The introduction shows that the compiler has consulted the report of the Committee on the Costs of Medical Care. She speaks of the majority report, and one minority report, though there were 2 of the latter.

The book opens with a Brief stating the question and summarizing the affirmative and negative sides. This we think is well done. Following this there are some 42 pages of bibliography. Some of the authors quoted are entitled to speak on account of their mentality and training. Just why others have been quoted, it is difficult to understand. The same thing may be said of the extracts which are given further on.

As a source book for those who are sufficiently in touch with the subject to judge of the value of the material presented and the qualifications of the authors quoted, it can be recommended. The subject is being discussed by all sorts of people, sociologists, philanthropists, doctors, etc. Unfortunately, a popular subject always attracts a number of people who like to be on the top of any wave of popularity.

MAZŸCK P. RAVENEL

National Medical Monographs—*Edited by Morris Fishbein, M.D. New York: National Medical Book Co. Vol. 1. Abnormal Arterial Tension—By Edward J. Stieglitz, M.S., M.D., F.A.C.P.,* 1935. 261 pp. Price, $3.00. *Vol. 2. Diseases of the Chest—By J. Arthur Myers, M.D.,* 1935. 385 pp. Price, $3.00. *Vol. 3. Commoner Diseases of the Skin—By S. William Becker, M.S., M.D.,* 1935. 283 pp.

Following a detailed table of contents, the author assembles his material in 16 chapters, illustrated by 66 figures, many of which are X-ray halftones, with a brief preface and quite adequate index. References are footnoted on the given page.

The subject falls into 4 general

phases—the normal vascular tension and its mechanism, the hypertensive, the hypotensive, and the relations to surgery and pregnancy. The public health worker will be especially interested in the chapters and discussion referring to etiology, prophylaxis, prognosis, and control-therapy. The early symptomless character of abnormal arterial tension, usually accompanied by a sense of well-being, and the great importance of recognition, in this stage, for proper control, emphasize the importance of periodic physical examinations and of preventive medicine which the author considers to be a purely individual problem—that is, one between the individual and his physician. Of significance are long continued mental fatigue, argumentative moods, tense play, cold and the "meal" effects, to say nothing of climate, race, physique, pregnancy, obesity, posture, infections, etc., and a legion of irritants and stimulants (and lack of same) which affect the muscles of the arterioles, constituting the underlying cause.

Such a thing as *idiopathic* or *essential* hypertension does not exist—a cause, perhaps more than one, always exists, and is quite invariably discoverable in the given case. Interesting tables classify these causes. A chart shows the causation of hypertensive arterial disease due to lead poisoning; another, the mechanism by which irritants finally produce arteriolar-sclerosis; etc. The hypertensive personality—the typical American—is a fine discussion. The nature and technic of tests are amply discussed.

We note a paucity of specific discussion on nutritional, *i.e.*, dietary, prophylaxis and therapy, though it is emphasized that the condition must be essentially a disturbance in nutrition. Perhaps the negative remark about the value of iodides and certain mineral elements (page 169) dismisses too lightly the relation of these elements to metabolism and the fundamental etiology. A special index summarizing references would no doubt have added to the usefulness of the volume, as appears in Clark and Drinker's *Industrial Medicine*, another of the monographs.

In summary, we have here a very readable and scientific text logically arranged with sub-heads, and covering a most momentous question in personal and public health.

In *Volume 2*, beginning with a detailed table of contents, the author assembles his material in 19 chapters, illustrated by 62 figures, mostly X-ray chest half-tones, with a brief preface and a combined index of authors and subject material. It has not been the purpose to cover the heart and thoracic vascular system. Part I covers the first infection type of tuberculosis (pathogenesis, tuberculin test, bronchoscopic and X-ray diagnosis, examination and classification, treatment, prognosis and preventives); Part II, reinfection type (establishment, acute and chronic types, management, artificial pneumothorax, operations and the magnitude of the tuberculosis problem); and Part III, non-tuberculous chest diseases (pneumonia, suppurative conditions, tumors, mishaps, moulds and yeast-like diseases, and pneumoconiosis). Each chapter ends with a summary and a list of references.

Public health workers having aught to do with pulmonary tuberculosis and its prophylaxis and management, including tests, accepted classifications, complications, and differential diagnosis, will find this a well balanced and valuable book written in clear-cut and convincing style. The same may be said for the non-tuberculous lesions such as those due to mould fungi, and the especially fine chapter on Diseases and Conditions Caused by the Inhalation of Dust, although in the latter possibly not enough space has been

given to the rapidly accumulating evidence that tuberculous involvement is difficult to substantiate in human cases of silicosis. Residual lesions and possible complications from the inhalation of irritant gases; and, in fact, the general subject of environmental predisposing and modifying factors, other than infestations and dust, are omitted. Hence, the stress of the presentation falls upon pathogenesis, diagnosis and clinical and surgical procedures, although the special chapter upon the magnitude of the tuberculosis problem recognizes the educational, economic and coöperative steps essential to the control of this disease.

In *Volume 3*, a brief preface points out that dermatology has passed through three eras: the *internist* (or internal factors) of the French school, the *externist* (or environmental factors) of the Viennese school, and the *bacterial*. The dawning era is the *biologic*. Man of all animals is the victim of dermatoses. The functional viewpoint and the lecture style are assumed in the present work. The volume comprises 26 chapters and 82 figures (all but 2, half-tones of skin conditions). There is no bibliography. The index comprises chiefly causal agents and subjects occurring in chapter sub-headings.

The work is preëminently one for the general practitioner of medicine who is being instructed by a specialist for the purpose of assisting him in his daily visitation by patients with all manners of skin and scalp troubles—a valuable *vade mecum* from etiology through diagnosis to therapy, including formulary. Outside of brief remarks upon the care of the skin and scalp, certain toxic and drug eruptions, and a half-a-dozen pages under the caption of The Skin in Industry, devoted chiefly to the rarer conditions, the work is quite beyond the average lay reader, as no doubt it should be. It should fill a definite need for the physician who wishes an up-to-date guide in the shape of a medium sized text, which is comprehensive and commendably free of verbosity. EMERY R. HAYHURST

Know Thyself: A Study in Mental Qualities—*By John Potts, M.D., D.C.L. Philadelphia: Dorrance,* 1935. Price, $3.00. 267 pp.

A philosophy of practical values and a study of the mind in action are here united in a plan for effective living which may be daily verified by observation of oneself and others. The simplicity of the language and the engaging style of the author make the book intelligible to the average man for whom it is written, while its unusual method of presentation and the subtile utilization of indirect suggestion might almost be said to guarantee its assimilation by the thoughtful reader.

The first 20 pages of the book are devoted to "The Problem," which is defined as the study, by the layman, of mental qualities of himself and others, with particular emphasis upon those qualities most to be desired. The last 23 pages are entitled "Progress," and are summed up in the concluding sentence of the book:

> A person who recognizes the mental qualities of men, women and children; who is intelligent enough to know what his social attitude, his duty, and his responsibility, if any, toward them should be, has acquired useful knowledge that will help him daily to pass through life with the maximum amount of pleasure and the minimum amount of grief.

"The Study," which comprises the remainder of the book, consists entirely of the 100 rules or observations on what constitutes *superior mentality,* together with the author's comments upon them. They reflect, he says, his experiences with people and his reading over years of time. A sampling of the rules will serve to indi-

cate their nature and variety, although it can give little idea of the penetrating wisdom of the discussion:

1. Persons having superior mentality have ability to see and to solve problems.
52. The social attitude of the superior mind is altruistic rather than indifferent, parasitic, or misanthropic.
100. The good mind has both will and ability to learn. In addition to these the great mind has great capacity for learning.

The author is to be congratulated on an outstanding contribution to the literature dealing with successful living, so much of which is of questionable value. The book is recommended to all "workers with men" for their personal enjoyment and profit and as an excellent volume to place in the hands of those who would increase their knowledge of themselves and achieve more happy, useful lives.

FREDERICK W. BROWN

A Geography of Disease: A Preliminary Survey of the Incidence and Distribution of Tropical and Certain Other Diseases—*By Earl Baldwin McKinley, M.D. Washington: George Washington University Press*, 1935. *Published as a supplement to the American Journal of Tropical Medicine.* 495 pp. Price, $5.00.

This preliminary survey of the incidence and distribution of so-called tropical diseases and certain other preventable diseases was prepared by Dr. McKinley as director of studies, with the coöperation of an advisory committee consisting of Frederick P. Gay, Richard P. Strong, and Theobald Smith, under the auspices of the Division of Medical Sciences of the National Research Council, and with the financial assistance of the American Leprosy Foundation. The object of the survey was to meet the growing need for more specific information concerning these diseases throughout the world. Data are presented from 15 of our southern states, and from nearly all the tropical and subtropical countries of the world. The collection of such information must necessarily have been extremely difficult in view of the fact that there exists no uniform method of recording or reporting the incidence of diseases in different countries, especially in those countries where tropical diseases are most prevalent, and where medical service and public health administration are in many cases poorly developed. The author and the committee are to be congratulated upon their courage and vision in attempting such a study.

The data were collected by means of a questionnaire sent to responsible authorities and by a study of official health reports. The results are given in the form of tables listing the presence or absence of individual diseases in each country now or previously; the distribution and approximate number of cases of each disease; the presence or absence of the vector, if any; and a statement as to whether the disease is considered an important health problem. Preceding the statistical material for each country is a brief statement concerning the geography, population, financial resources, principal products, climatic conditions, and special disease problems. Following the statistical section of the book is a series of summaries of selected tropical diseases with short articles by well known authorities concerning the problems involved in the control of these diseases. Finally, there is an appendix which records other interesting information which was not suitable for inclusion in the main body of the book.

The difficulty of obtaining uniformly accurate information either by a questionnaire or from official reports is evident from the statistical material presented. In many cases it

was necessary to supplement the answers to the questionnaires by an examination of the annual reports of health departments. Some of the tabular data cover definite periods of time, usually 1 or 2 years, while in other cases only the date of the filling out of the questionnaire is given. The reports used to supplement the questionnaire apparently varied widely in the amount of detail presented. In some cases these reports included all the mortality and morbidity statistics of the political unit concerned while others recorded only the statistics of the public health laboratory. This lack of uniformity in the source of data makes it impossible to compare with any degree of accuracy the incidence of diseases in different states or countries. Despite this defect the survey is valuable in giving a general idea of the distribution of diseases and pertinent data concerning the regions in which they occur.

It is obvious from the incompleteness of the data presented that there is a great need for a better and more uniform system of collecting morbidity statistics in this country and throughout the world. Practitioners must be induced to coöperate better in reporting diseases, and health departments must institute more accurate and uniform terminology. It is deplorable, for instance, that the species of malaria parasite is not more generally recorded, and that often no distinction is made between bacillary and amebic dysentery, nor the term amebiasis used to cover all conditions due to *E. histolytica*. It is to be hoped that this survey will help to stimulate this much desired improvement.

It is difficult to see how a survey of this kind could be made with any degree of completeness without the services of a large staff organized for the collection of morbidity statistics. Many national governments as well as the League of Nations already publish statistics on the incidence of a number of important diseases, but there is an increasing need for those organizations to devise methods whereby similar data may become available for all preventable diseases. If the present report can serve as a start for such an accomplishment it will have served a good purpose. It will serve as a valuable source of information to those interested in the distribution of the important diseases of warm countries and should indicate where such diseases can best be studied.

HENRY E. MELENEY

The Bacteriology of Typhoid, Salmonella, and Dysentery Infections and Carrier States—*By Leon C. Havens, M.D. Edited by Kenneth F. Maxcy, M.D. Foreword by Wilson G. Smillie, M.D. New York: The Commonwealth Fund. London: Humphrey Milford. Oxford University Press,* 1935. 172 pp. Price, $1.75.

Here is a book that summarizes knowledge gained through years of practical experience in the specialized and complicated field of the enteric diseases and sets this against a theoretical background gained by intensive reading and study. No bacteriologist in this country has had more actual laboratory experience with this group of bacteria than Dr. Havens, who served for 11 years as Director of the several Alabama State Laboratories in a territory where the endemic incidence of diseases of this group is particularly high. Few bacteriologists have specialized in the literature of this field to the same extent as Dr. Havens, as evidenced by his analytical discussions of the claims of various investigators found scattered throughout the book, and by the extensive bibliography appended to each chapter. From this rare combination there emerges this text which is more than

a guide to the bacteriology of the group—it is a guide to clear thinking regarding the problems presented by these organisms.

Thirteen chapters comprise the book, of which the first 3 deal with general aspects of the bacteriology of the group. Here is an excellent discussion of the antigenic composition of the cell and of bacterial variation as it affects physiological and serological characteristics of the various organisms. The explanation of the "diphasic" phenomenon and of the somatic changes in antigenic composition are illustrated by excellent, clear-cut, and yet simple, drawings. Five chapters deal with laboratory methods and, while Dr. Havens naturally favors those he developed and used so successfully in his years of work, he does not present them alone but offers alternative ones and in many instances presents tables of comparative results. He devotes 2 chapters each to a consideration of the 3 groups: Typhoid fever, Salmonella, and Dysentery, with special reference to the correlation of laboratory findings with clinical and epidemiological facts. The typhoid carrier problem is discussed and a plan presented for the organization and management of carrier surveys. His discussion of the classification and nomenclature of the Salmonella group is exceptionally clear and illuminating, as is his presentation of the antigenic relationships of the various strains of dysentery bacilli.

The book is attractively printed and arranged, reflecting the excellent editing of Dr. Maxcy. A short summary is presented at the end of each chapter. It should have a wide circulation not only among laboratory workers and investigators but also in the classroom and among those administrators and epidemiologists who are called upon to interpret the results of laboratory studies in these diseases.

In studying this book one cannot but feel how unfortunate it is that the brilliant brain of Leon C. Havens had to be stilled by his untimely death at the age of 41 years. EDMUND K. KLINE

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH.D.

For the Treatment of Pneumonia—Studies in typing and treating pneumococcic pneumonias carried on by the Massachusetts State Health Department, and a review of modern methods for attacking the vexing pneumonia problem are described in non-technical language.

ANDERSON, G. W., and HEFFRON, R. Present Status of Pneumonia Problem. Pub. Health Nurs. 27, 12:633 (Dec.), 1935.

Food, Hormones and Sunlight—In this series of lectures on nutrition the author describes, among other studies, the examination of infant excreta to determine how much of various foods added to the infant's diet are absorbed. This work may have been done in this country too, but, if so, it has not been reported in the journals most health workers see.

ARMAND-DELILLE, P. Problems of Nutrition and Growth. J. State Med. 43, 12:683 (Dec.), 1935.

The Right to Marry—Beginning with this year, Connecticut couples may not obtain a marriage license until they obtain a medical certificate indicating freedom from syphilis.

BURGDOFF, A. L. Social Significance of the New Marriage Law. Connecticut Health Bull. 49, 11:247 (Nov.), 1935.

Influenza Epidemiology—Ten influenza outbreaks occurring during the past 15 years are studied and the progress recorded in graphs.

COLLINS, S. D., and GOVER, M. Influenza and Pneumonia Mortality in a Group of about 95 Cities in the United States during Four Minor Epidemics 1930–35 with a Summary for 1920–35. Pub. Health Rep. 50, 48:1668 (Nov. 29), 1935.

About Cancer Causes—Though this brief summary of existing beliefs and disbeliefs in regard to the many causes of cancer is labeled "partial," it seems really inclusive. Health workers generally would profit by a close reading of this easily understood survey which urges more detailed clinical study of cases.

CRAVER, L. F. Etiology of Cancer. J.A.M.A. 105, 23:1820 (Dec. 7), 1935.

Safeguarding Ice Cream Manufacture—Food poisoning on shipboard from ice cream made with preserved chestnuts was studied. *Staphylococcus aureus* probably was the causative organism, and insanitary practices in preparing the food were probably to blame.

GEIGER, J. C., *et al.* Food Poisoning from Ice Cream on Ships. J.A.M.A. 105, 24:1981 (Dec. 14), 1935.

Undulant Fever and Raw Milk—Evidence is presented indicating that an outbreak of undulant fever was caused by drinking raw milk from diseased cows which were infected with the strain from swine.

HORNING, B. G. Outbreak of Undulant Fever Due to Brucella Suis. J.A.M.A. 105, 24:1979 (Dec. 14), 1935.

Why Syphilis Is Not Stopped—All the deficiencies in public health preventive measures against syphilis are set down in 1-2-3 order and the chips are allowed to fall where they may. All administrators should read this.

STOKES, J. H. The Public, the Doctor, and the Syphilis Problem. J. Social Hyg. 21, 7–8–9:313 (Oct.-Dec.), 1935.

Evidence for Poliomyelitis Vaccine—Steps leading to the trial of attenuated poliomyelitis virus upon human beings and the record to date are described in absorbing detail.

KOLMER, J. A. Susceptibility and Immunity. J.A.M.A. 105, 24:1957 (Dec. 14), 1935.

Against Poliomyelitis Prophylaxis—A round dozen cases of poliomyelitis occurring 6 to 14 days after the injection of poliomyelitis virus, none of the patients being in epidemic areas or known to have been exposed, would appear to make further immunizations unwise.

LEAKE, J. P. Poliomyelitis Following Vaccination against the Disease. J.A.M.A. 105, *26:2152* (Dec. *28*), 1935.

A Farm Editor Looks at Rural Health—Seeing our larger jobs as others see them is a wholesome experience. The hits, runs, and errors of rural public health and medicine in the United States and Canada are chalked up by an unprejudiced critic for all to observe.

STREETER, C. P. Reorganizing Rural Health Facilities. Pub. Health Nurs. 27, 12:638 (Dec.), 1935.

Sugar and Nutrition—When at the beginning this paper indicated its concern with the dangers of sugar in the diet, a silent bet was made that cancer would be dragged in before the score was completed. Sure enough, one authority quoted suspected sugar of being a possible cause of hypertension and arteriosclerosis, as well as cancer. According to the statistics given as of 1928, United States did not stand first in per capita consumption of sugar; three other countries exceeded it.

WALLACE, W. H. S. The Place of Sugar in the National Diet. Pub. Health, 49, 3:84 (Dec.), 1935.

ASSOCIATION NEWS

PROFESSIONAL EDUCATION

THE Professional Education Committee of the American Public Health Association under the chairmanship of W. S. Leathers, M.D., of Nashville, Tenn., met in New York on January 4, with a complete attendance of the members and good representation from sub-committees interested in several of the schedules under consideration for health department personnel.

New members of the committee who were present included Henry F. Vaughan, Dr.P.H., of Detroit, and Stanley H. Osborn, M.D., of Hartford, Conn.

The entire day was spent in formulating broad policies for Association activities, several progress reports being received from sub-committees for later consideration and editorial revision by a special committee. Consideration of the qualifications of health officers was deferred for a later meeting.

THE NEW MEMBERSHIP APPLICATION BLANK

THE discontinuance of the associate membership grade necessitated the printing of new membership application blanks. The new form is a decided improvement over the old one in that it provides for more information qualifying the applicant for election to membership.

Please give the new form the welcome it deserves by writing to the central office for a copy and handing it to some coworker who is not yet a member of the American Public Health Association.

APPLICANTS FOR MEMBERSHIP

The following individuals have applied for membership in the Association. They have requested affiliation with the sections indicated.

Health Officers Section

R. D. Dedwylder, M.D., Cleveland, Miss., Director, Bolivar County Health Dept.

Frank C. Diver, M.D., Raton, N. Mex., District Health Officer

James N. Dudley, M.D., Henrico County Health Dept., Richmond, Va., Health Officer

Thomas H. D. Griffitts, M.D., D.P.H., State Board of Health Bldg., Jacksonville, Fla., Surgeon, U. S. Public Health Service

Frances A. Kenyon, M.D., Woodrille, R. I., Health Officer

Stanley Mattmiller, 226 Chestnut St., St. Marys, Pa., County Health Officer

Lester F. Meloney, M.D., 156 Second St., Clifton, N. J., Health Officer

Laboratory Section

Ruth M. Cowdell, Box 1139, Hartford, Conn., Senior Assistant Serologist, State Dept. of Health

Robert A. Greene, Ph.D., P. O. Box 4694, Tucson, Ariz., Director, Arizona State Laboratories

John J. Phair, M.D., C.P.H., State Board of Health, Jacksonville, Fla., Acting Director, State Laboratory

Vernon L. Turgasen, 8015 Carpenter St., Chicago, Ill., Quality Supervisor, Armour & Co.

Seth T. Walton, V.M.D., Ph.D., City Health Dept., Charlotte, N. C., Director of Laboratories and Research

Public Health Engineering Section

Milton H. Bidwell, B.S., 171 Evans Ave., Freeport, L. I., N. Y., Bacteriologist, Sanitary Control of Shellfish

Edwin D. Cushman, M.S.P.H., 1113 Grant

Vital Statistics Section

Lidie C. Venn, A.B., 39 Lynwood Place, New Haven, Conn., Fellow of National Tuberculosis Assn.

Food and Nutrition Section

Abraham E. Abrahamson, Ph.G., 200 E. 16 St., New York, N. Y., Inspector of Foods, Dept. of Health

Charles F. Church, M.D., 4025 Huey Ave., Drexel Hill, Pa., Research in Nutrition, School of Medicine, University of Pennsylvania

Herman W. Erde, B.S., 415 Ditmas Ave., Brooklyn, N. Y., Supervising Inspector of Foods, New York City Dept. of Health

J. A. Keenan, Ph.D., Wisconsin Research Foundation, Madison, Wis.

Captain Michael Shipley, D.V.M., 1601 N. Ballinger St., Fort Worth, Tex., Veterinary Officer, U. S. Army

Child Hygiene Section

Joyce I. Hartman, M.D., Board of Education, Cleveland, O., Directing Supervisor, Medical Service, City Public Schools

Guy N. Magness, M.D., 6701 Delmar, University City, Mo., School Physician, City Public School

Public Health Education Section

Mrs. Ernest R. Grant, Hay-Adams House, Washington, D. C., Managing Director, District of Columbia Tuberculosis Assn.

Sister Marie, R.N., Regis College, Weston, Mass.

Marion Simonson, R.N., 353 W. 57 St., New York, N. Y., Field Adviser in Public Health, State Committee on Tuberculosis and Public Health

Public Health Nursing Section

Gladys A. Adams, R.N., 226 E. Fordham Rd., Bronx, N. Y., Executive Secretary, Bronx Tuberculosis and Health Committee

Lena Gaudet, R.N., 170 Elm St., Amesbury, Mass., Public Health Nurse

Anna R. Moore, R.N., 1410 Alaska Bldg., Seattle, Wash., State Advisory Public Health Nurse

Hilga S. Nelson, 297 Walnut St., Newtonville, Mass., Executive Director, District Nursing Assn.

Johanna L. Sogaard, State Board of Health, Jacksonville, Fla., District Supervisor of Nurses

Olive M. Whitlock, R.N., 816 Oregon Bldg., Portland, Ore., State Advisory Nurse

Epidemiology Section

Harold E. Miner, M.D., 65 Columbus Ave., Holyoke, Mass., District State Health Officer

NEWS FROM THE FIELD

DR. PARK RETIRES

DR. WILLIAM HALLOCK PARK, F.A.P.H.A., ex-President of the Association, noted bacteriologist and hygienist, retired on his 72nd birthday anniversary, December 29, from his position as Director of the Bureau of Laboratories of the Department of Health, New York City, the position which he has held for the last 41 years. This announcement was made by Dr. John L. Rice, Commissioner of Health, on December 26.

Under this arrangement Dr. Park will take a 6 months' vacation, after which he will retire permanently from the directorship and become Director-Emeritus of the Bureau. The new William H. Park Research Laboratories named in his honor are expected to be completed within a few months so that they can be dedicated while Dr. Park is still in the city's service. He will continue to work in the laboratory in an advisory capacity.

The new Acting Associate Director, Dr. Ralph Muckenfuss, member A.P.H.A., will be in charge during Dr. Park's absence.

As Professor of Bacteriology and Hygiene at the University and Bellevue Hospital Medical College since 1897, Dr. Park has been an active contributor in the field of public health. Among his connections he has been consulting bacteriologist and medical examiner in bacteriology for the New York State Department of Health and has been consulting bacteriologist for the U. S. Quarantine Service. He was president of the American Public Health Association in 1924 and has been vice-president of the New York Academy of Medicine. He has been widely honored for his researches in preventive medicine, with particular reference to diphtheria, tuberculosis, and poliomyelitis.

PSITTACOSIS VICTIM

A RECENT report from San Francisco states that Karl F. Meyer, M.D., F.A.P.H.A., head of the Hooper Foundation of the University of California, is recovering from psittacosis, which he contracted two months ago while engaged in extensive experiments to check the spread of the disease.

DR. CLARK RECEIVES MEDAL

THE American Chemical Society, New York Section, has announced that the William H. Nichols Medal, a highly prized honor, has been awarded to Dr. William Mansfield Clark, Professor of Physiological Chemistry at Johns Hopkins University School of Medicine, for 1936, "for researches of incalculable value to human welfare."

The medal will be presented to Professor Clark at a dinner meeting of the New York Section on March 6, when Dr. D. D. Van Slyke of the Rockefeller Institute and Dr. A. Beard Hastings of the Harvard Medical School will discuss these achievements, following which Dr. Clark will deliver the annual Nichols Medal address. Among previous recipients of this medal were Dr. Irving Langmuir, Nobel prize winner in chemistry, and President James Bryant Conant of Harvard University.

Dr. Clark is a graduate of Williams College and received the degree of Ph.D. in chemistry from Johns Hopkins in 1909. From 1910 to 1920 he was research chemist with the Dairy

Division of the U. S. Department of Agriculture and from 1920 to 1927 he was associated with the U. S. Public Health Service as Professor of Chemistry and chief of the division at the Hygienic Laboratory.

HOSPITAL SURVEY OF NEW YORK CITY

A COMPREHENSIVE hospital survey for New York City has been organized under the direction of the United Hospital Fund of New York under a grant of $40,000 from the Carnegie Corporation. A general committee of 100 representative citizens has been chosen and the direction of the survey has been placed in a Study Committee under the chairmanship of Dr. George E. Vincent. Other prominent members of this committee are: Dr. S. S. Goldwater, Dr. Charles Gordon Heyd, Dr. John E. Jennings, Dr. Eugene H. Pool, Dr. Willard C. Rappleye and Dr. Nathan B. Van Etten. Dr. Haven Emerson, who has directed other major community hospital surveys, is the Director of the Study.

PLANS FOR CHILD HEALTH DAY

THE Conference of State and Provincial Health Authorities has assumed the responsibility previously carried by the American Child Health Association for Child Health Day plans. A permanent committee has been appointed to handle the matter. The Secretary of this Conference is A. J. Chesley, M.D., F.A.P.H.A., State Health Officer, St. Paul, Minn.

PENNSYLVANIA TUBERCULOSIS SOCIETY

THE Pennsylvania Tuberculosis Society will hold its annual meeting at Allentown, Pa., on February 26. Speakers will include Dr. Edith MacBride-Dexter, the Secretary of Health of Pennsylvania, and Professor C.-E. A. Winslow, of Yale University.

OHIO HEALTH CONFERENCE HELD

THE 16th Annual Conference of Health Commissioners with the Ohio State Department of Health was held in Columbus, O., Nov. 13–15.

Included among the guest speakers were: J. A. Myers, M.D., of Minneapolis, Minn., member A.P.H.A., on Tuberculosis; Eugene L. Bishop, M.D., of Knoxville, Tenn., F.A.P.H.A., on Health and Sanitation in the Tennessee Valley; Martha M. Eliot, M.D., of Washington, D. C., on Maternal and Child Health; John Collinson, M.D., Dr.P.H., of the U. S. Bureau of the Census, Washington, D. C., F.A.P.H.A., on Vital Statistics; and J. A. Doull, M.D., of Cleveland, O., F.A.P.H.A., on A Survey of the State Health Department.

IMMUNIZATION DRIVE IN IOWA

STATE and local health authorities in Polk County, Ia., are coöperating with parent-teacher associations and other agencies in a campaign to immunize children against diphtheria.

It has been decided to devote one month each year to this campaign. This year it began in November, and is being publicized by radio, newspapers, and speeches. Much of the educational work is being undertaken by the Des Moines Council of Parent-Teacher Associations.

PHYSICIANS' PLACEMENT BUREAU

THE American Association of School Physicians recently established a placement bureau to aid physicians meeting its qualifications to find desirable positions, and to recommend to educational institutions medical inspectors qualified to organize and administer an efficient program of health service and health education.

For information, write to the Director of the Bureau, Arville O. DeWeese, M.D., formerly president, Director of

Health and Physical Education, Kent State College, Kent, Ohio.

NEW HEALTH UNIT IN ALABAMA

THE establishment of the Henry County Health Department on a full-time basis brings the total number of these full-time units in Alabama to 56.

The new unit will begin functioning January 1.

WPA TUBERCULOSIS CAMPAIGN IN DISTRICT OF COLUMBIA

WITH $99,000 available from the Works Progress Administration, a campaign to eradicate tuberculosis in the District of Columbia has begun.

X-ray machines have been made available in the city of Washington for the taking of roentgenograms by means of the paper method. Physicians may refer patients either for an initial film or for a check on treatment, all the work to be done without cost to the patient.

RHODE ISLAND PUBLIC HEALTH ASSOCIATION INCORPORATED

ON January 7, 1936, the Rhode Island Public Health Association was incorporated under the laws of the state and held its first annual meeting. The first president elected was Dr. Edward A. McLaughlin, the State Director of Public Health of Providence.

GRADUATE STUDY ABROAD

THE Institute of International Education located at 2 West 45th Street, New York, has a publication, *Opportunities for Graduate Study Abroad Open to American Students*, which is available on request. The Institute also supplies pamphlets on fellowships and assistantships available in transatlantic countries, and a bulletin, *Fellowships and Scholarships Open to American Students for Study in Foreign Countries*, is available at a cost of 25 cents.

COSMETIC SAMPLES IN MAINE

COSMETIC manufacturers have filed approximately 2,500 samples of their varied products with the Department of Health and Welfare, Augusta, Me., in an effort to have their products salable under Maine's new cosmetic law, effective January 1. Cosmetics kept for unlawful sale or use are subject to forfeiture. The registration fee has been reduced from $1 to half that amount.—*Printers Ink*, Jan. 2, 1936.

DR. FLEXNER REAPPOINTED

ON January 6, Governor Herbert H. Lehman, of New York, reappointed Dr. Simon Flexner, of New York City, as Chairman of the State Public Health Council. Two new members to the Council were appointed, Dr. Clayton Greene of Buffalo and Dr. George Baehr of New York City. Dr. Herman G. Weiskotten, dean of the Syracuse University Medical School, was named to succeed Dr. Frederick F. Russell, formerly of Brooklyn, who resigned.

The Public Health Council of New York State is charged with the duty of formulating the New York State Sanitary Code.

MEXICAN ACADEMY OF MEDICINE ELECTS NEW OFFICERS

THE National Academy of Medicine of Mexico announces the following new officers, elected recently:

President—Dr. Gustavo Baz
Vice-president—Dr. Ignacio González Guzmán
Secretary (permanent) — Dr. Alfonso Pruneda
Secretary (annual)—Dr. Mario Quiñones
Treasurer—Dr. Manuel Martínez Báez

TVA HEALTH

EFFECTIVE January 1, the responsibilities of the Tennessee Valley Authority in Health, Sanitation, Medical and Safety are being administered through a newly established Division of Health and Medical Service under the direction of E. L. Bishop, M.D., F.A.P.H.A., as Director of Health.

In the past, these responsibilities have been discharged through three sections in two different divisions, but under the administration of a single division director, Dr. Floyd W. Reeves, who served as the administrative officer of both divisions. The new division was created at the suggestion of Dr. Reeves who is changing his status from that of an administrative officer to consultant, and safety was included because of its close functional relationship to the other services.

RED CROSS RECEIVES BEQUEST

UNDER the will of Mrs. Clara A. Hapgood Higgins Smith, the American Red Cross will receive $3,482,535, according to a statement disclosed on December 27 when the transfer tax appraisal was filed in the New York court. The Red Cross is the residuary legatee in the will.

Other bequests by Mrs. Smith, who was a resident of Allegany County, N. Y., included local hospitals, the New York State Charities Aid Association, the Stony Wold Sanitarium at Lake Kushaqua, N. Y., and the Association for Improving the Condition of the Poor, New York City.

BACTERIOLOGICAL AWARD

AN annual award of $1,000 will be made to a young man or woman for distinguished work in bacteriological research, it was announced at the closing session of the 37th Annual Meeting of the Society of American Bacteriologists in New York. A feature of the award, which is expected to become the principal American recognition of achievement in this field, is that it will be given only to research workers in college or university laboratories who are younger than 31.

The first winner will be announced at next year's meeting in Indianapolis. Recognition will be given to original work either in bacteriology or in immunology, and a group of scientific societies have been asked to share in its sponsorship. The American Association of Immunologists and the American Society for Experimental Pathology have already agreed to coöperate in selection of the winner. The prize has been guaranteed for the next 5 years by the Eli Lilly Company, biological manufacturers of Indianapolis.

CONNECTICUT CANCER STUDY

IT is stated that the Connecticut State Department of Health will soon begin a study of the mortality and the prevention and treatment of cancer, in accordance with an act passed by the last legislature at the recommendation of the State Medical Society.

The Bureau of Preventable Diseases will carry on the study, and Herbert F. Hirsche, of Hamden, Conn., member A.P.H.A., has been appointed Research Statistician for the work.

FULL-TIME UNIT IN INDIANA

THE first full-time county health department in Indiana has recently been set up in Lake County. The 1935 general assembly passed a law permitting the establishment of full-time county health units and the Lake County commissioners adopted a resolution setting up the new unit. In addition, provision was made for one sanitary inspector, one stenographer and clerk, and four public health nurses, all employed full time, effective January 1.

William D. Weis, M.D., of Crown Point, Ind., is Health Commissioner.

DENTAL DESENSITIZER

ALL dentists without restrictions may obtain the dental desensitizer which was discovered in the laboratories of the Columbia Dental School by Dr. Leroy L. Hartman. It will not be patented, Frederick Coykendall, chairman of the board of the university, has announced.

The desensitizer is a liquid applied to the dentin of the tooth, and is effective for more than twenty minutes.

Dr. Hartman's formula, which has been the goal of dental research since the practice of modern dentistry began, aids the science by lessening the pain that occurs in the preparation and filling of tooth cavities.

AWARD TO MRS. THOMPSON

AT its 61st annual meeting held on November 15, 1935, the New Jersey Health and Sanitary Association awarded to Mrs. Geraldine Livingston Thompson a certificate " in recognition of her outstanding accomplishment in promoting the welfare of the people of New Jersey through her interest and activity in public health and social welfare."

This annual award is given by the association in such a form that it attracts public notice to service rendered in public health and related fields.

PERSONALS

HANS ZINSSER, M.D., Sc.D., Fellow A.P.H.A., was named on January 8 to the new Charles Wilder Professorship of Bacteriology and Immunology in the Harvard Medical School, Boston, Mass.

DR. W. A. MCPHAUL has been appointed State Health Officer of Florida by Governor Sholtz. Dr. McPhaul has been full-time County Health Officer of Escambia County, Fla., for several years. He was formerly connected with the North Carolina State Board of Health and was Health Officer of Charlotte, N. C. Dr. McPhaul succeeds Dr. Henry Hanson, F.A.P.H.A.

NAOMI DEUTSCH, R.N., F.A.P.H.A., has been appointed Director of Public Health Nursing Activities of the Children's Bureau in Washington. Miss Deutsch goes from the University of California in Berkeley to act as consultant for the important public health nursing projects under the auspices of the Children's Bureau. She is chairman of the Public Health Nursing Section of the Association.

DR. FRANCES C. ROTHERT, member A.P.H.A., formerly of Hartford, Conn., has been appointed to the Children's Bureau, U. S. Department of Labor, with responsibility for a group of states in the southern portion of the United States.

DR. DORIS A. MURRAY, formerly of Rochester, N. Y., has been appointed to the Children's Bureau and will represent the Bureau in certain of the eastern states. Dr. Murray has been on the staffs of the Maryland State Department of Health and the Cattaraugus County Department of Health, N. Y.

DR. SARA DIETRICH, recently of the staff of the New York State Department of Health, has been appointed to the Children's Bureau, U. S. Department of Labor, to be in charge of a group of states in connection with the new Social Security program.

DR. ROBERT C. HOOD, formerly of Parkersburg, W. Va., has been appointed director of crippled children's work with the Children's Bureau, U. S. Department of Labor, Washington. Dr. Hood has for some years been in the practice of pediatrics in West Virginia.

DR. JOHN R. BRUCE, of Marshfield,

Mo., has been appointed Health Commissioner of Webster County. He formerly served as County Physician.

DR. RANSOM L. CARR, of Rose Hill, N. C., has been appointed Health Officer of Dublin County, to succeed Dr. Clarence H. White, of Kenansville, resigned.

DR. HERBERT D. CHAMBERLAIN, of McArthur, O., has been appointed Health Commissioner in charge of a new health unit in Vinton County.

DR. WILLIAM GROSSMANN, JR., of Petersburg, Va., has been appointed Assistant Epidemiologist in the Virginia State Department of Health.

DR. SHOCKLEY D. GARDNER, of South Boston, Va., has been appointed Health Officer of the Valley Health District, with headquarters in Harrisonburg.

DR. JAMES N. DUDLEY, of Danville, Va., has been appointed Director of the Henrico County Health District, with headquarters in Richmond.

DR. THOMAS B. PAYNE has been appointed Health Officer of Fredericksburg, Va., to succeed the late Dr. Justus Lee Cooke.

WILLIS C. BEASLEY, formerly of Johns Hopkins University, Baltimore, Md., is in Alabama, establishing headquarters for 4 states now being studied in the national survey of health conducted by the U. S. Public Health Service. Montgomery has been designated regional headquarters for Alabama, Georgia, Louisiana, and Texas.

DR. CARL A. PETERSON, of Moline, Ill., has been named a District Superintendent of Health on the staff of the Illinois State Health Department. Moline will be his address.

DR. HARRY A. YEAGER has recently been appointed Health Officer of Litchfield, Ill.

DR. SOPHIE B. D. EBERLE, recently of New Haven, Conn., has been appointed in charge of the Pueblo Indians in the vicinity of Albuquerque, N. M.

DR. FRANK C. DIVER, of Springer, N. M., has been appointed Health Officer of the Ninth New Mexico Health District.

DR. DANIEL L. SECKINGER, formerly Epidemiologist for the Georgia State Department of Health, has been appointed Assistant Health Officer for the District of Columbia.

DR. SAMUEL J. DICKEY, who has been on the staff of the Pennsylvania State Department of Health for about 10 years, has been appointed Medical Director of Chester County, Pa.

DR. HOWARD F. STRAUB, of Selingrove, Pa., has been named Medical Director of Snyder County, Pa., succeeding Dr. Russell W. Johnston.

DR. DUNN HAMILTON ROW, of Indianapolis, Ind., sailed November 1, for Shikarpur, Baluchistan, India, where, with 4 other eye specialists, he will conduct an eye clinic.

DR. CHARLES E. HOLLAND has been appointed Health Officer of Bloomington, Ind., succeeding Dr. Russell A. DeMotte.

LAWRENCE W. BASS, PH.D., Fellow A.P.H.A., Director of Research of the Borden Company, has been elected Chairman for 1936 of the New York Section of the American Chemical Society. He succeeds Professor Arthur W. Hixon, of Columbia University.

HERMAN N. BUNDESEN, M.D., of Chicago, F.A.P.H.A., is a Democratic candidate for Governor in Illinois.

ABBOTT B. MITCHELL, M.D., member A.P.H.A., has recently severed his connection with the Allegan County Health Department, Allegan, Mich., and has taken a position with the Michigan State Department of Health as Director of the Bureau of County Health Administration.

HUGH S. CUMMING, M.D., Fellow

A.P.H.A., Surgeon General of the U. S. Public Health Service, Washington, D. C., has been appointed one of an executive committee of ten, named by the Health Section of the League of Nations at its recent meeting in Geneva, Switzerland.

ELSBETH VAUGHAN, of St. Louis, Mo., F.A.P.H.A., was recently awarded the Nightingale Medal by the International Committee of the Red Cross, Geneva, Switzerland.

DR. MARION F. HARALSON, Senior Surgeon, U. S. Public Health Service, is now Acting Secretary of the Colorado State Board of Health, in the absence of Roy L. Cleere, M.D., member A.P.H.A., of Denver, Colo., who is at the School of Hygiene and Public Health of Johns Hopkins University, Baltimore, Md.

THOMAS F. O'BRIEN, M.D., member A.P.H.A., has been appointed Acting Health Officer for the City of Hartford, Conn., succeeding Charles P. Botsford, M.D., F.A.P.H.A., who retired after 27 years' service.

DR. JOHN A. BUCCIARELLI has succeeded Myron J. Brooks, M.D., member A.P.H.A., retired, as Health Officer of New Canaan, Conn.

DR. MICHAEL D. RIORDAN has been appointed Health Officer of Windham, Conn.

DR. CHARLES MOLINE, of Sunderland, Mass., was recently chosen President of the Franklin County Public Health Association.

JOHN L. LAVAN, M.D., F.A.P.H.A., for 4 years Director of the Department of Public Health and Welfare of Kalamazoo, has resigned to become Commissioner of Public Health of Grand Rapids, Mich.

DR. CHARLES WALTER CLARKE, Medical Director of the American Social Hygiene Association of New York, member A.P.H.A., has been appointed temporary Director of the Bureau of Venereal Disease in the New York City Department of Health.

DR. RILEY H. MILLER, of Ulysses, Kans., has been named Health Officer of Grant County.

LOUIS C. KRESS, M.D., member A.P.H.A., Director of the New York State Division of Cancer Control, has been appointed Chairman of the State Cancer Committee of the American Society for the Control of Cancer, succeeding Dr. Burton T. Simpson.

DR. EDMOND H. SAUVIGNET, of Laredo, Tex., has been appointed Health Officer of Webb County, succeeding Dr. Albert T. Cook, who became Health Officer of the City of Laredo.

DR. ROBERT W. GORDON has been appointed Deputy Manager of Health and Charity of the Health Department of Denver, succeeding Bertram B. Jaffa, M.D., F.A.P.H.A.

DR. JAMES B. UNGLES, of Satanta, Kans., has been appointed Health Officer of Haskell County, succeeding the late Dr. Loring V. Miner.

DR. WILLIAM J. SCOTT, of Ottawa, Kans., was recently placed in charge of the Franklin County Health Unit.

DR. PAUL T. THIBODAUX, of Donaldsonville, has been appointed Health Officer of Donaldsonville, La.

DR. JOHN A. SKLADOWSKY was recently promoted to be full-time Medical Health Officer in the Baltimore Health Department and was assigned to the Western Health District. He has been connected with the Department since 1920.

HARRY GARLAND TIMBRES, M.D., member A.P.H.A., has been appointed assistant in biostatistics at Johns Hopkins University School of Hygiene and Public Health, Baltimore, Md.

FRANK A. KIERNAN, member A.P.H.A., former Executive Secretary of the Massachusetts Tuberculosis League, has been named Director of the New York Tuberculosis and Health As-

sociation. He fills the position left vacant by the resignation of Harry Hopkins two years ago to become Federal Emergency Relief Administrator.

DR. HARVEY J. SKARSHAUG, of Guthrie Center, Ia., has been appointed Health Officer of Fargo, to succeed Burton K. Kilbourne, M.D., Fellow A.P.H.A., who resigned to become State Epidemiologist of Montana.

DR. V. D. KERNS, of Duncan Falls, Ohio, has been appointed Health Officer of Pickaway County, succeeding Dr. Charles C. Beale, of Circleville, resigned.

DR. SAMUEL W. SHELTON, of Guin, Ala., has been appointed Health Officer of Winston County.

DR. GEORGE E. NEWTON, of Fayette, Ala., has been appointed Health Officer of Jackson County, to succeed Dr. Edward A. Thorne, resigned.

DR. PAUL G. SHELL, of Marianna, Fla., was recently placed in charge of a new health unit in Jackson County.

DR. FRANK V. CHAPPELL, formerly of Madison, Fla., has been appointed Health Officer of the Jacksonville District, succeeding Dr. Thomas E. Morgan.

DR. RALPH J. SYKES, of Jackson, N. C., has been appointed Health Officer of Surry County, to succeed Dr. James Allen Whitaker, of Rocky Mount, resigned.

ALFRED D. GREGG, M.D., member A.P.H.A., of Tarboro, N. C., has resigned as Health Officer of Edgecombe County.

DR. FRANCIS EDGAR MAHLA, of Marion, Ohio, has been appointed Assistant State Director of Health, succeeding James E. Bauman, member A.P.H.A., who had held the position 43 years.

DEATHS

FRANCIS X. MAHONEY, M.D., Fellow A.P.H.A., Health Commissioner of Boston, Mass., almost continuously for more than 20 years, died January 14, at the age of 64 years.

DR. KATHARINE BEMENT DAVIS, of Pacific Grove, Calif., died December 10, at the age of 75 years.

CONFERENCES

Feb. 3–15, Institute for Training of Tuberculosis Workers, under the auspices of the National Tuberculosis Association, New York; to be held at New York University, Washington Square, New York.

Feb. 26, Annual Meeting of the Pennsylvania Tuberculosis Society, Allentown, Pa.

Mar. 2–6, Twentieth Annual Session of the American College of Physicians, Detroit, Mich.

Apr. 1–3, American Water Works Association—Canadian Section, Hamilton, Ont.

Apr. 22–25, National Tuberculosis Association, New Orleans, La.

May 11–15, American Medical Association Convention, Kansas City, Mo.

May 14–16, American Water Works Association—Pacific Northwest Section, Aberdeen, Wash.

June 24–27, Seventh Annual Meeting, Western Branch, A.P.H.A.—meeting simultaneously with Canadian Public Health Association—Vancouver and Victoria, B. C.

June 8–12, 56th Annual Convention, American Water Works Association, Los Angeles, Calif.

July 6–11, The Royal Sanitary Institute, Southport, England.

July 25–Aug. 1, The Second International Congress of Microbiology, London.

July 27–31, Second International Congress on Mental Hygiene, Paris.

Sept. 8–10, International Union Against Tuberculosis, Lisbon, Portugal.

Oct. 29-31, Annual Meeting of the Association of Military Surgeons, Detroit, Mich.

Application for Membership

I wish to apply for membership in the American Public Health Association.

Safe
Swimming Pools

EVERSON pools are safe pools. For over a quarter of a century EVERSON has led in the development of safer swimming pools and equipment . . . the Re-circulating System that keeps water pure. Underwater Lighting and the EVERSON Safety Electric Chlorinator that ends hazards of pressure drums, of gas leaks, etc., that manufactures at the pool the "perfect chlorine" as needed to maintain germ free pool water at all times. These and many other important developments (everything for the pool) illustrated and described in New Free Catalog. Write for your Catalog today.

Positions Wanted

HEALTH OFFICERS

Experienced health officer, M.D., Dr.P.H., Johns Hopkins graduate, is available for position. 201

Physician, trained and experienced in health organization activities, sanitation, epidemiology, tuberculosis, venereal investigations, industrial hygiene, hospital administration, etc., seeks position as health officer. Will consider any locality. 202

Gentleman, M.D. University of Pennsylvania, is immediately available for a public health administrative position. Has served as medical director for school inspection service, city health officer, instructor in public health at a well known college and as epidemiologist for a state health department. 203

Physician, experienced county health officer and state epidemiologist, seeks position as health officer or epidemiologist with state or city department of health. 190

Gentleman, M.D., Dr.P.H., University of Pennsylvania, excellent background, desires position as health officer or in other public health administrative capacity. Has served as full-time county health officer, city health officer, assistant state health commissioner, state epidemiologist, and has established and developed a state bacteriological laboratory. 195

M.D., Director of a health unit and public health laboratory, wishes position as commissioner of health or its equivalent. Missouri or Eastern states preferred. 196

Health officer with medical and public health degrees is available for position. Has been director of a county health department. 200

TECHNICIANS

Woman, Vassar graduate, D.Sc. in hygiene with major in immunology, Johns Hopkins University, seeks laboratory work. Has served as instructor in bacteriology and immunology at Vassar and Johns Hopkins and was director of a state hygienic laboratory for six years. 173

Young woman, bacteriology and chemistry major, M.S., desires position with university, hospital, health department or manufacturing company. Experienced laboratory and research assistant in parasitology, histology and serology in a Class A medical school. 193

NURSES

Unusually well-qualified public health nurse, capable of state-wide supervision with ample field experience and full academic background, is available for appointment. East or Middle West preferred. 194

Public health and school nurse, 10 years' experience, wishes position as public health or school nurse or in tuberculosis work. Registered New York and Pennsylvania. 192

MISCELLANEOUS

Physician, graduate of Washington University Medical School, desires position with state department of public health to do educational writing on mental hygiene, child guidance or venereal diseases. Capable of group instruction in health education. 197

Exceptionally well-qualified physician, long experience in social hygiene educational programs, is available for appointment at once. Internationally known author of texts on this subject. 198

Experienced statistician, woman, Cornell University graduate, is available for opening in the statistical field. Has worked on the staff of a city and state health department as well as on special projects. 199

Where no other address is given excepting the key number, address your replies to the American Journal of Public Health, 50 West 50th Street, New York City, indicating clearly the key number on the envelope. Your replies will then be forwarded.

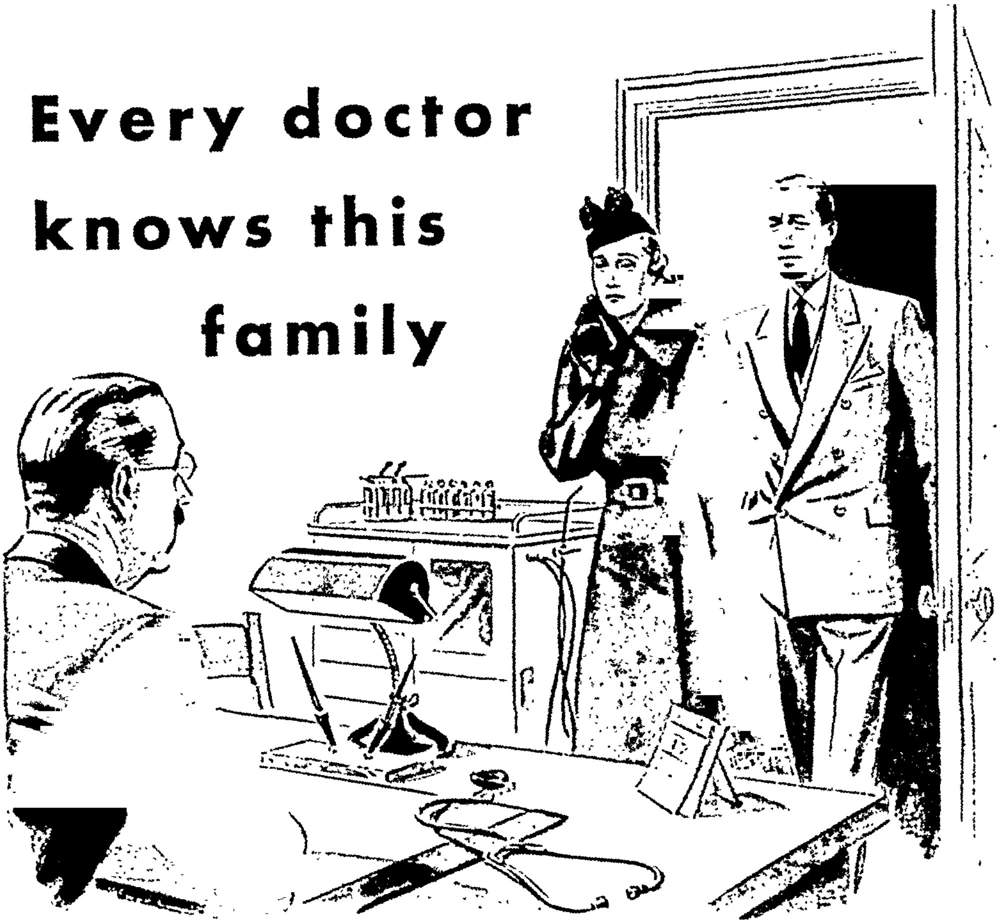
Every doctor knows this family



THEY visit him off and on. They're not actually sick, but never quite well. They lack the vitality they should have. Compared with others, their personalities seem colorless. His questioning frequently reveals common constipation, due in most cases to insufficient "bulk" in their meals.

Addition of "bulk" to the diet is often indicated. But tests have shown that, in some cases, the "bulk" in fruits and vegetables is broken down in the alimentary tract. This does not happen with bran.

Kellogg's ALL-BRAN provides an abundance of gentle "bulk." Also vitamin B and iron. It may be served as a cereal or made into appetizing muffins, breads, waffles, etc. ALL-BRAN is much more effective than part-bran products.

This wholesome product is accepted by the American Medical Association Committee on Foods. ALL-BRAN is sold by all grocers. Made by Kellogg in Battle Creek.

The natural food
THAT CORRECTS CONSTIPATION

Typhoid Vaccine Studies*

Investigation of Virulence and Antigenic Properties of Selected Strains of the Typhoid Organism

THE LABORATORY STAFF, ARMY MEDICAL SCHOOL, UNDER THE SUPERVISION OF J. F. SILER, M.D.

Colonel, Medical Corps, U. S. Army; Director, Army Medical School, Washington, D. C.

THE use of typhoid vaccine for individual prophylaxis was first introduced into the United States on a large scale by General F. F. Russell, of the U. S. Army. The preliminary studies were made by him at the Army Medical School, in Washington, D. C., and, after thorough investigation of such work in England and Germany, production of vaccine was begun in 1908. The following year vaccination was commenced in the Army as a voluntary measure; it became applicable to all military personnel in 1912.

The strain of the typhoid bacillus selected for the preparation of the vaccine was the well known Rawlings strain isolated by Wright in 1900 and used by Leishman for the preparation of the British Army vaccine. The original technic of preparation here combined the German saline suspension of agar cultures with the British method of counting, of killing at a relatively low temperature, and of preserving with cresol. Although minor changes have been made occasionally, the technical procedures have remained essentially the same throughout the years. The Rawlings strain is still in use.

From time to time suggestions have been made to the effect that a change in technic, such as: that the use of formalin for killing and preserving would reduce reactions and preserve the original antigenic qualities of the vaccine, or that the use of a different strain—a freshly isolated strain, or several strains—of the typhoid bacillus would improve the immunizing potency of the vaccine. Such suggestions have always received serious consideration, as evidenced by the recent thorough discussion of the subject by Hawley and Simmons.

That the vaccine as it has been prepared, using the Rawlings strain, is efficiently immunogenic has been amply demonstrated by the trend of typhoid fever in the U. S. Army and the U. S.

* Presented by Major A. Parker Hitchens, M.C., before the Laboratory Section of the American Public Health Association at the Sixty-fourth Annual Meeting in Milwaukee, Wis., October 10, 1935.

Navy following its introduction as a preventive measure. With the record achieved, it is obvious that any change in the method of preparation of the vaccine or in the strain of bacillus used must await thorough study of all factors involved. Before any modification can be considered seriously there must be ample proof, gained by a dependable method, that through it the vaccine will be no less protective than it has been in the past. The development and production of the Army typhoid vaccine is a major function of the Army Medical School. It is, therefore, in conformity with this duty that the investigations now under way were undertaken. They relate to studies of selected strains of the typhoid bacillus, the purpose in view being the utilization of all recent developments in bacteriology and in immunology to determine when, and how, it may eventually be practicable to improve still further the protective qualities of the typhoid vaccine prepared for and used by the Army, Navy, and other government bureaus as a protective measure.

Great credit must be given to Grinnell for his originality in applying to the direct evaluation of virulence and immunogenic potency of vaccine strains a method which has been at our disposal for many years. He used the intraperitoneal injection of mice to study the relation of the killing power of various strains of the typhoid bacillus to their immunizing activity, and correlated these factors with their colonial and antigenic structural characteristics. In this work he brought together and used to a practical end those recent developments in the study of bacteriology which might otherwise have remained nothing more than intensely interesting and possibly controversial research phenomena. The result of Grinnell's work is that we now have an experimental method which may give us an approach to the standardization of typhoid vaccine.

THE STRAINS OF EBERTHELLA TYPHOSA CONCERNED

From the numerous strains available 7 were finally selected for this work. Each of them is representative of the group to which it belongs; together they include the types of typhoid bacilli most under discussion at present.

1(I)

This is the Army Medical School culture of the English Rawlings strain which was brought to the United States by General F. F. Russell in 1908. Since 1910, it has been used in the preparation of typhoid vaccine at the Army Medical School. Subsequent to the observations of Arkwright it has been considered an intermediate form, being neither completely rough nor typically smooth. The colonies grow rapidly, are round or nearly so, with smooth edges sloping upward to a slightly raised center. Under 5X magnification colonies have a slightly roughened appearance. In consistency, they are moist and homogeneous. When grown in broth a uniform turbidity is produced; the growth on agar is easily made into a stable uniform suspension in saline. It is actively motile. The majority of the bacilli are of average size with the variations usually seen in old stock cultures—individuals vary from short, almost coccal or oval to long, curved forms.

The average lethal dose* (a.l.d.) for mice is approximately 400 million organisms in Ringer's solution suspension. In mucin suspension the m.l.d. is approximately 100 million in Swiss mice.

1(R)

This is a typical rough variant of 1(I) obtained from the agar transplant

* Average lethal dose (a.l.d.) is defined as the number of bacilli which have been found to kill 50 per cent of the mice injected; m.l.d. is that which kills 100 per cent. In this work mature, white mice weighing 18 to 20 gm. have been used. The observation period is up to and including 72 hours.

of a 17 day old infusion broth culture of the latter. The colonies are rapidly growing, flattened, with irregular margins, and roughened surfaces. In consistency, they are dry and granular. Growth in broth is luxuriant, with pellicle formation and sedimentation, the intervening medium being clear or only slightly clouded. While growth on agar is abundant, a uniformly turbid suspension of it in saline is made only with difficulty. The suspension agglutinates spontaneously forming flakes of varying size. In hanging drop the bacilli are seen to be actively motile; stained preparations show atypical forms, many of them being large, thick, curved rods. The young organisms, while typical bacilli in form, are larger than those of the same age of the parent strain.

The a.l.d. for mice is approximately 400 million organisms in Ringer's solution suspension.

1(s)

A typical smooth form of 1(I) obtained from the agar transplant of a 17 day old infusion broth culture of the parent organism (isolated in 1931). The colonies grow slowly and are considerably smaller than 1(I) colonies. They are round, with even margins and smooth surfaces, characterized by a heaped center giving the colony the geometrical appearance of a half-sphere. In consistency they are moist and homogeneous. Growth in broth produces uniform turbidity, and the growth on agar is easily suspended in saline. The bacilli are actively motile; in stained smears they are indistinguishable from those of the parent culture.

The a.l.d. for mice is approximately 400 million organisms in Ringer's solution suspension.

53

Isolated from the blood of a mild case of typhoid fever, at Walter Reed General Hospital, in May, 1932. The blood serum of the patient contained both flagellar and somatic agglutinins. Colonies are round, of medium size, have raised centers, and slightly irregular margins from which ridges begin, converging to the center. The consistency of the colonies is moist and homogeneous. This strain produces uniform turbidity in broth; the growth on agar is easily suspended in saline. It is actively motile; there is nothing characteristic on a stained film.

The a.l.d. for mice is approximately 300 million organisms in Ringer's fluid suspension.

36

Isolated in October, 1933, from the blood of a patient at Walter Reed General Hospital. Clinically a very toxic type of infection. No flagellar and little if any somatic agglutinins could be demonstrated in the patient's serum. Moreover, the latter failed to agglutinate this organism. It was an O inagglutinable strain.

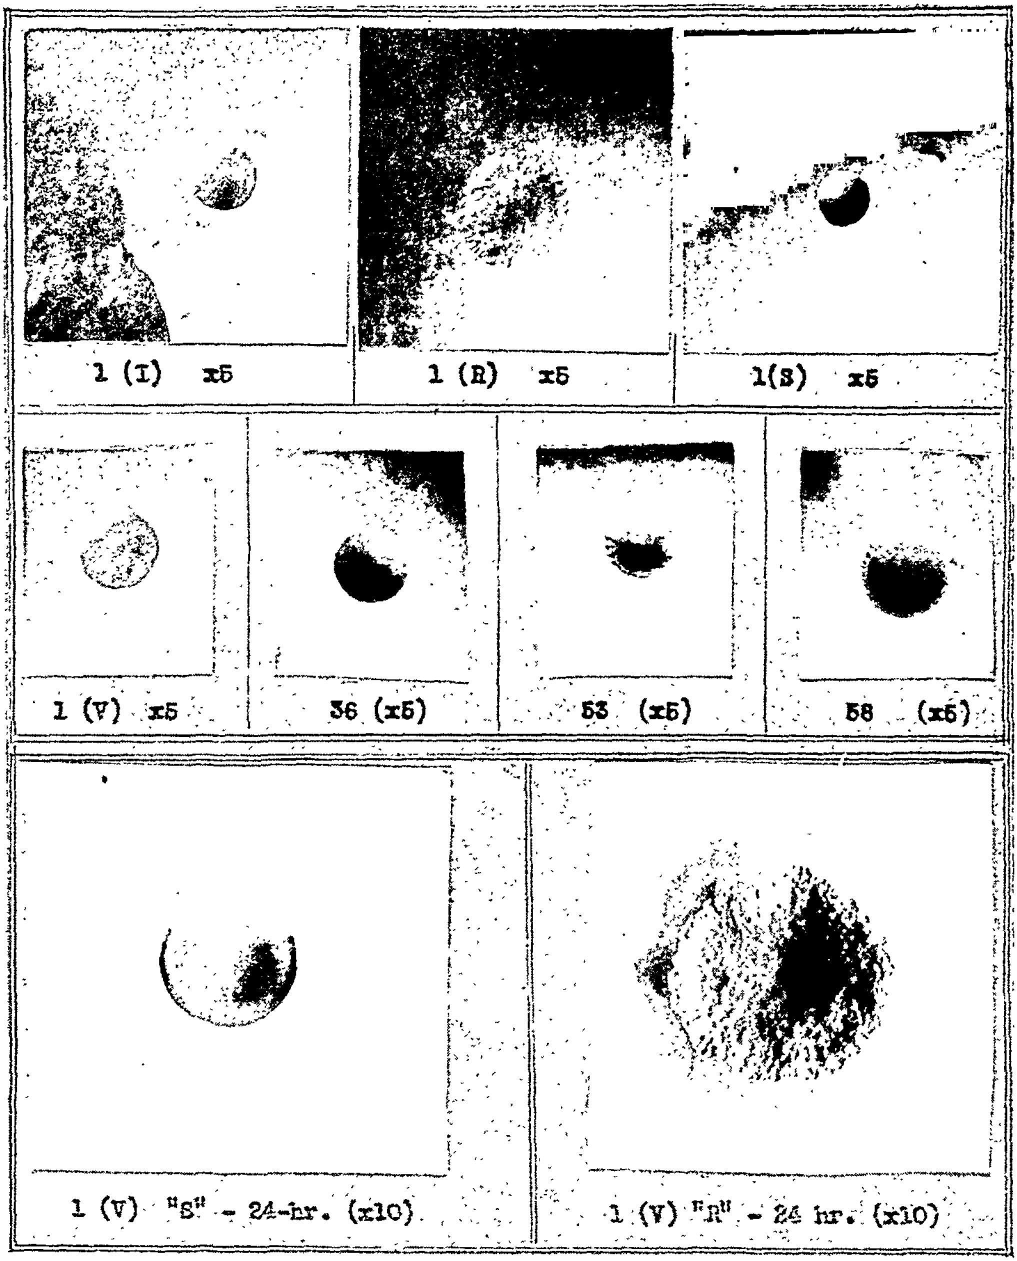
Colonies are round and dome-shaped, with smooth margins and surfaces, of medium size, and characterized by a translucent brownish center. Consistency, moist and homogeneous. It produces uniform turbidity in broth; growth on agar is easily suspended in saline. The bacilli are actively motile, and the individuals are of uniform, but slightly smaller than average size.

The a.l.d. for mice is approximately 75 million organisms in Ringer's fluid suspension.

58

The "Panama Carrier Strain," isolated in September, 1934, from the feces of a carrier (attack of typhoid fever in 1913) in Panama, by Dr. L. B. Bates. The colonies are larger than average, round, with sides sloping gradually to raised, flat centers; the margins are slightly crinkled; the consistency is moist and homogeneous. Growth in broth produces uniform turbidity; growth on agar is easily suspended in saline. The bacilli are actively motile;

TYPICAL COLONIES OF STRAINS OF E. TYPHOSA USED IN THIS WORK



NOTE: Colonies in upper block, 1(I) to 58, 18 hours old.

a stained preparation shows them to be small, short rods, uniform in size.

The a.l.d. for mice is approximately 100 million organisms in Ringer's solution suspension. In mucin suspension the m.l.d. is 100 bacilli, in Swiss mice.

1(v)

Rawlings-Bensted. A rejuvenated (by mouse-passage) race of the Rawlings strain, obtained from Colonel Perry of the R.A.M.C., Netley, England, in October, 1934. The colonies produced by this culture grow rapidly, they are large, round, and perfectly smooth. Growth in broth produces uniform turbidity; the moist and homogeneous growth on agar is easily made into a uniform and stable suspension in saline. The bacilli are actively motile, although non-motile colonies have been encountered in this study. A stained preparation shows them to be small rods, uniform in size.

The a.l.d. for mice is approximately 75 million organisms in Ringer's solution suspension.

PRESERVATION OF STRAINS

In order that strains shall remain without change, at least, until the completion of these studies, special measures have been taken to provide against the differences likely to occur in routine cultivation. In January of this year, prior to the commencement of the virulence tests, each strain was frozen and dried by the method of Flosdorf and Mudd. The growth from agar cultures after suspension in veal infusion, peptone broth (pH 7.4) was distributed into sterile, pyrex ampules. The am-

pules were immersed in alcohol chilled to about –78° C. by means of CO_2 snow, then they were attached to the manifold and suction applied by means of a vacuum pump. Drying of the suspension was effected without thawing. After 5 to 6 hours, during which time a high vacuum was maintained, the ampules were sealed off in a blow pipe flame—without breaking the vacuum. They were stored in a refrigerator whose temperature is about 5.0° C. Up to the present no change of any kind has been detected in the strains preserved in this way.

TESTS FOR TOXICITY OR VIRULENCE

These tests were carefully planned in order that the bacteria of the various strains would be of the same age at the time of their injection. This required the coöperation of the entire technical staff of the Army Medical School. To insure thorough understanding on the part of everyone a " dry run " was enacted the day before the first series of tests was made.

The cultures, grown exactly as for the production of typhoid vaccine, were suspended in buffered Ringer's solution when they were from 18 to 20 hours old. The suspensions were then counted in a Helber counting chamber; the average of at least 3 counts was considered as giving the greatest accuracy obtainable.

The suspensions were then diluted to the desired strength with buffered Ringer's solution. The dose for a mouse was adjusted so that in every instance it was contained in 0.5 c.c. of fluid. This amount was injected intraperitoneally, the skin of the mouse being first touched by a cotton swab moistened with alcohol. Tuberculin syringes of 1.0 c.c. capacity were used; these carried a 5/8" –25 gauge needle. Great care was taken to see that the injected mice were properly fed and watered.

Two sets of tests were made—a preliminary and a final. In the preliminary test, lots of 5 mice each received the same dose. Five different doses were injected for each strain. The information desired was the a.l.d. for each strain. This is the number of bacilli which will kill 50 per cent of the mice. Table I shows the results of the preliminary tests.

The information gained was used in estimating the range of dosage for the final tests. In this, 5 different amounts were injected. The amounts were adjusted so that the a.l.d. might fall at the middle dose. For the lowest and the highest doses 10 mice were injected and 30 for each of the 3 intermediate doses. The counting and method of injecting were identical with those of the preliminary tests. The results are shown in Table II.

VACCINE PROTECTION TESTS

Having determined the a.l.d. for each of the 7 strains the next point was to use this information to determine the relative protective value of vaccines made from them. The tests were planned so that the protective potency of the vaccine of each strain would be ascertained not only for itself but for each one of the other strains. In other words, cross-protection tests were made in all directions. Furthermore, the extent of the protection was ascertained by testing against not only one, but also against multiples of the a.l.d. In this, as in the virulence tests, there were a preliminary and a final series of tests.

The vaccines were made exactly as the regular typhoid vaccine is made, routinely, in the Army Medical School. They were standardized so that the first dose was 100 million, the second and the third 200 million typhoid bacilli. These amounts were contained in 0.25 c.c. of the vaccine. Injections were made intraperitoneally at weekly intervals. Two weeks subsequent to the final dose the test injections were given as in the virulence tests. The results of the prelim-

inary immunization test are shown in Table III.

This may be considered a satisfactory result. The first dose for each strain in the protection test was estimated to be one-half the a.l.d. In other words, it was the intention to have for each group of 5 vaccinated mice an amount below that expected to kill more than 2 of them. That things did not turn out exactly according to the plan is merely one more illustration of the wide limits of accuracy, resulting from several uncontrollable factors, attainable in such work. On the other hand, a high percentage of the control mice died and a high percentage of the vaccinated mice lived. Furthermore, the indication is clear that vaccines made from strains 58, 36, and 1(V) afforded better protection than did the others.

Another interesting factor suggested by this series is that mice which received living bacilli belonging to strains 1(I), 1(R), 1(S), and 53 were not protected so well as those which received as their test dose bacilli of strains 36, 58, and 1(V). One explanation for this is immediately apparent when we note the enormous numbers of bacilli it was necessary to inject when testing with members of the avirulent group.

The information gained from careful study and discussion of these preliminary cross-immunity tests was used in planning the final one. In this the conditions were identical with those of former tests. Planting of cultures on the day prior to the injection of the test doses of living organisms, was so timed as to make the whole chronological set-up uniform. The injections were

97.7% of the deaths among the normal mice occurred during the first 24 hrs.
The remainder, or 2.3% were dead at the end of 48 hours.

made by a uniform technic, and the mice were cared for subsequently as were those of the previous lots. The total number of mice used in this series was 6,200, and they were all injected between 8:00 A.M. and 3:00 P.M. The results are shown in Table IV.

Examination of this table gives in probably a more satisfactory and conclusive manner the same information as that gained from the preliminary cross-protection tests. The death rate among the controls was closer to the ideal. In the case of 58 and 1(V) the results might have been even more convincing if the dosage had been somewhat higher.

It is quite clear that we are dealing with two different groups of strains so far as virulence is concerned. In the tests with living bacilli of the relatively avirulent group it appears that the dosage was so high that differences in protective value of the vaccines were almost obliterated. When we examine the results among the groups which received as their test doses bacilli of the

more virulent strains, however, wide differences in the protective value of the vaccines are apparent. Here again the strains are clearly grouped. The strains 36, 58, and 1(V) are more efficiently immunogenic than are 1(I), 1(R), 1(S), and 53.

DISCUSSION

In such work as this one is constantly seeking to differentiate between toxicity and virulence and between these terms and invasiveness. The last, it is believed, should be restricted to cases in which the animal species concerned is susceptible to natural infection by the organism concerned; to cases in which, by some means, the microörganism gains access to the tissue for which it has a special predilection and develops there eventually causing morbidity and possibly mortality. The sickness most frequently exhibits a characteristic clinical picture. The type of clinical syndrome usually depends upon the characteristic metabolic products of the infectious process.

It is not so easy to separate virulence from toxicity. In any case, toxicity is not a good word to be employed in so vague a manner. Ehrlich defined the

word toxin so clearly and definitely that its use in any other sense is really not admissible. The trouble is that we have no other term to express the idea here. In the injection of enormous doses of relatively avirulent typhoid bacilli we have almost overwhelmed the mice by a mass of noxious or "toxic" material which gives their acquired vaccinogenic immunity no chance to demonstrate its existence. The differences in immunity which we do discover are the result of combinations of noxiousness or "toxicity" and virulence in which the former is not sufficient to overwhelm the animal. On the other hand, it acts somewhat like an "aggressin" and prepares the mouse for a result dependent upon whatever virulence the particular strain of relatively avirulent bacilli may have.

CONCLUSIONS

There seems to be some indication in these results that immunogenic properties of typhoid organisms are associated with their virulence. The virulent organisms used in this experiment, when used as a heat-killed tricresol preserved vaccine in the number of mice tested, gave better protection than that afforded by the avirulent group under similar circumstances.

Laws, Dealer's Insurance

. . . Instead of protesting against health legislation, the informed milk dealer is one of its most ardent advocates. Aside from his interest as a citizen, he is concerned in a selfish way with the maintenance of standards which will guard the milk supply from any suspicion of being a carrier of disease. Let him think for a moment what it would mean to him if an epidemic were traced to the milk supply of even some small unimportant peddler, to say nothing of what it would mean if one of the large milk concerns were implicated. Attach the stigma of milk-borne infection to even the smallest route and the whole milk industry in that area suffers. Orders are cancelled by the thousands and it is no easy task to convince frightened mothers that their children are safe if they drink the milk of a concern which is not involved in the outbreak. Why, health laws are the best insurance the milk trade can have!

. . . Most large milk distributors, for a purely selfish reason, leave nothing undone to safeguard the purity of their product. But sometimes the small concern or the producer-distributor might not be so careful since, having less investment in the business, he has less to lose and might be more willing to take a chance. Rigidly enforced milk regulations prevent him from taking that chance and thus serve as a safeguard not only to the public health but to every other farmer who produces milk in that area, and every other man who distributes it. There may be laws which seem to serve no worthy purpose but they are comparatively few in number and the burdens they inflict are offset a hundred times over by the value of the good ones. If public health authorities were to announce tomorrow that every regulation governing the sale of milk were to be removed, not 10 days would elapse before leading dealers would be attempting to do, voluntarily, what the laws now require them to do. The only difference is that they could not do the job half so well.—Editorial, *The Dairy Record,* Jan. 8, 1936.

Plumbing Hazard Survey of Pasteurization Plants*

W. SCOTT JOHNSON, F.A.P.H.A.

Sanitary Engineer, Division of Health, St. Louis, Mo.

THE excellent study by the Chicago Health Department culminating in the definite determination of the cause of a striking epidemic of amebic dysentery, has caused many city health departments to become much more attentive to defective plumbing and its health significance. Although sanitary and public health engineers had for a number of years appreciated the dire potentialities of such defects, crystallized interest and demand for effective control were lacking until this epidemic forced the issue in a dramatic and thoroughly convincing manner. Many studies and surveys have been made of faulty plumbing by various agencies and, although complete reports are not available, apparently the studies have been largely confined to hotels and similar buildings, probably because the Chicago epidemic was centered in two hotels having faulty plumbing.

The author, in carrying out a preliminary survey of plumbing in buildings used for a number of purposes, included milk pasteurization plants. It is the purpose of this discussion to bring to attention the potential dangers of the contamination of milk from faulty plumbing in pasteurization plants.

SCOPE AND PLAN OF SURVEY

This investigation was made possible through engineers provided by the professional FERA program. The program was planned on the basis of an investigation or demonstration as required by the FERA. The work was carried out in a systematic manner in order to discover all existing plumbing defects, and as accurately as possible the nature of such defects.

Graduate engineers, with few exceptions unfamiliar with sanitary engineering methods and technic, were available. Considerable time and effort were spent in training them by lectures, field inspections, and literature. Survey blanks for recording information were prepared and a system of standard sketches of piping systems was devised so that defects could also be shown and checked diagrammatically. In the beginning it was arranged that each investigator should spend ample time with an experienced man, so the details of the work were thoroughly understood. Weekly or more frequent conferences were held with all the men in attendance, at which points in question were thoroughly discussed. Upon the completion of a plant the investigators, working in pairs, prepared a written report covering the significant sanitary details. With these data available the work was completely field checked by the most competent and experienced man in direct charge of the work. Sam-

* Read before the Public Health Engineering Section of the American Public Health Association at the Sixty-fourth Annual Meeting in Milwaukee, Wis., October 10, 1935.

ples of the potable water supply were collected from several outlets in each building and analyzed bacteriologically.

Engineers making the surveys were allotted, in accordance with FERA regulations, a varying number of work days each month which obviously did not lead to maximum efficiency. Table I indicates the number of milk plants surveyed, time required, and cost of field work.

TABLE I

PASTEURIZATION PLANT EQUIPMENT

In order more readily to interpret the results of this survey, it is essential to discuss briefly milk plant equipment and plumbing requirements.

A modern milk plant is concerned with the processing of milk and milk products for the market. Pasteurized fluid milk and cream, butter milk, cultured milk, cheese, and ice cream constitute the principal end products. For the manufacture of these products various types of equipment are necessary, such as pasteurizers, coolers, holding vats, churns, condensers, refrigerators, compressors, brine tanks, bottle and can washers.

Large quantities of water are essential for washing, rinsing, cooling, the generation of steam for power, and sterilizing purposes. It is common practice to rinse equipment with water before milk or milk products are placed in contact with surfaces. Usually the initial cooling is accomplished with tap water and it is not uncommon for the shell or pipe wall separating this cooling medium from the milk to develop leaks. Frequently a product such as butter is washed direct in tap water. Cooling water is used over and over with the aid of roof aerators which are exposed to aerial contamination. Condensers are often employed for cooling the refrigerating medium with tap water, which is used repeatedly with the aid of aeration, or discharged to waste through a solid connection to the sewer. Toilet facilities are provided to maintain satisfactory personal hygiene. It is apparent that the quality and the quantity of the plant water supply are two important items in safe and effective operation.

Provision is made for the disposal of waste water from such plants by means of the usual system of sewer lines. The contents of these lines consist of the sewage from toilet rooms as well as large volumes of waste water from washing and rinsing machinery, floors, and other appurtenances. These sewers carry potentially infectious material and at times are probably overloaded to the extent of producing internal pressure.

RESULT OF SURVEY

The result of a survey of the plumbing and piping systems of 6 milk plants indicated a situation that was extremely complicated, especially in the large plants. The many types of equipment concerned, the frequent maze of pipes, and the various ways that this equipment was inter-connected with water and sewer lines, presented many difficulties in obtaining accurate information. To simplify and clarify the results of the survey the defects found have been grouped into 6 general types according to the way in which the condition becomes a plumbing defect and potential health hazard. "Plumbing defect" is used in a broad sense to include faults in piping systems as well as equipment design.

Type 1—Direct pipe connection between potable water supply and sewage or other contaminated water, with or without check or manual valve between, which through excessive back pressure or negative head, or both, might result in the contamination of the potable supply with sewage or polluted water. Example Type 1—Polluted water pump directly connected to potable water supply, condensers directly connected to potable water supply and also to sewer lines; drains or overflow from potable water tanks directly connected to sewer lines; mechanical refrigerating, units directly connected to potable water supply and sewer lines. Figure I illustrates this type of defect.

Type 2—Potable water supply inlets constantly submerged or submerged because of direct or indirect stoppage that, due to a negative head or vacuum in the potable water supply lines, might result in the contamination of the potable water supply with sewage or polluted water through back siphonage. Example Type 2—Constantly submerged inlets which are hazardous even when the fixtures are in good operating condition; such as siphon jets in water closets and urinal traps, laundry washing machines, processing tanks, water softeners, and stockwater basins. Inlets not ordinarily submerged beneath the surface of the fixture contents but which at times become submerged due to carelessness in filling or to stoppage of outlets; such as flushing rim openings in water closets, urinals, and slop sinks, lavatories, utility room sinks, drinking fountains, bottle washers, loose hose, etc. Figure I illustrates this type of defect.

Type 3—Sewer lines located over pasteurizers or other milk processing equipment; floor drains located in refrigerators or other rooms where food is stored or processed and in rooms where ice is made or prepared for use. Figure I illustrates this type of defect.

Type 4—Water supply subject to aerial pollution. Example Type 4—Potable water supply tanks with open or loose tops or covers located on roof of building or other exposed location.

Type 5—Possible infection of persons through use. Example of Type 5—Faultily designed drinking fountains which can be contaminated by user and result in a hazard to subsequent users.

Type 6—Equipment designed to hold food during processing, surrounded by or containing pipes or jacket through which the water supply is circulated. Frequently this type of equipment is rinsed with tap water just previous to use. The danger from such connections and operation is predicated upon the water supply becoming contaminated due to other faulty plumbing and the development of breaks in the pipes or jacket so that contaminated water would leak into the food supply. Example Type 6—Certain types of milk pasteurizers, milk holding vats, milk coolers, and other equipment in which dairy products are heated or cooled or both.

Based on this grouping of plumbing defects Table II indicates the number of plumbing defects in each milk plant.

Table III indicates the extent to which equipment is involved in various types of plumbing defects.

The number of defective connections found and the extent to which equipment was involved varied greatly depending largely on the size of the plant. Tables IV and V indicating the survey data on 2 milk plants illustrate this wide variation.

In 2 instances samples of water collected from milk plants showed heavy contamination. In 1 case, an auxiliary spring water supply, cross-connected with the city water supply and also used for cooling and flushing purposes within the plant, showed contamination. In the second instance the water sample was taken from a supply line to a milk cooler.

The survey of 6 milk plants showed the existence of 210 plumbing defects. There were 28 different kinds of milk plant equipment involved in the hazardous connections found. In 152 instances the plant water supply was subject to possible contamination. Forty-three pieces of equipment were found with water jackets or coils which in case of a leakage would allow the plant water supply to come into contact with the milk. In 137, or 65 per cent, of the defects found, back siphonage and in some cases stoppage of outlets, would be necessary to cause a hazard. Ten, or 4.8 per cent, of the defects resulted from direct connections, that is, solid piping without a break existing between contaminated water or sewage and the potable water supply.

DISCUSSION

It seems probable that the contamination of the milk plant water supply

or some milk product may occur due to the various types of plumbing defects revealed by this survey. The frequency of such an occurrence cannot, however, be determined. The modern health officer is constantly seeking to provide more complete prevention against the contamination of foods. The public health importance of safely handling milk, during the vital process of pasteurization, is evident. Likewise, no effort should be spared to protect public water supplies from contamination.

As far as the more adequate protection of public milk supplies from filth-borne diseases is concerned, many city and state health departments and the U. S. Public Health Service have made notable progress, particularly in the last 10 years. Considerable effort and large sums of money are continually being expended to safeguard further the production of milk, its transportation, and processing by the distributors. It would appear that in our endeavor to improve upon pasteurization, cooling, and other equipment, as well as methods and supervision, the existing system of plumbing in milk plants, and certain details of milk equipment design, have been accepted as satisfactory without sufficient investigation.

It is recognized that at least a partial vacuum may exist without warning in any water piping system due to a number of causes such as a heavy draft in a

main due to a fire, or cutting off the water supply and draining lines for repairs. Such a vacuum has been shown to be capable of siphoning the contents of a flush valve type toilet bowl, in good working order, into the water supply line.

The usual method of protecting potable water lines directly connected to contaminated water or sewer lines against pressure on the non-potable water side from a pump, or back pressure due to the temporary stoppage of surcharging in a sewer line, has been by means of a check or manual valve. The ease and frequency with which such valves are made ineffective by corrosion, stoppage by foreign substances, or even tampering by the careless or uninformed, render their protection very uncertain. In general, these faults of piping or plumbing systems are responsible, in a great variety of modifications, for most of the existing potential hazardous plumbing conditions. The public health reasons for keeping sewage or human fecal material from contact with food or a potable water supply, are too well understood by health officials as well as the public, to require further discussion.

The results of this survey reveal a number of ways in which water supply, milk, and milk products in all the plants surveyed might be contaminated. If the water supply of the plant becomes contaminated with sewage because of one of the above reasons, there are many possibilities of this pollution coming in contact with milk due to leaks in coolers or pasteurizers. Whenever water is used in direct contact with milk products, such as butter, or rinsing surfaces of milk equipment, the danger is obvious. There is also the ever present danger of this contaminated plant water supply back-flowing into the distribution system. Additional examples of a hazardous situation in milk plants is the location of sewage lines directly over equipment used to process milk products, and the dangers due to leakage from joints or corroded pipes.

Many of these defects are obscure and require public health engineering training for their detection as well as rectification. It is a fact also that usually a sequence of unanticipated events must occur to make the potential defects an actual health hazard. This only emphasizes the difficulty of the problem since it creates an entirely false impression of safety.

Certain types of plumbing connections are more dangerous than others. Likewise the type and age of buildings, equipment, maintenance of equipment, and other factors, all have a bearing on the possibility of a health hazard occurring. Direct connections between a contaminated and potable plant water supply with excessive pressure on the contaminated side may be assumed as the most dangerous from the standpoint of possible frequency of occurrences. On the other hand, back-siphonage of the contents of flush toilets would usually be most dangerous from the standpoint of the greatest concentration of infection.

Old plumbing, badly corroded, and lacking many modern safeguards, as well as a poorly maintained piping system, present great potential hazards. Besides defective plumbing, this survey indicated that milk plant equipment is improperly designed in many cases, and may be responsible for contamination of the water supply or milk products.

In general, it is believed that the technical problems involved, and the financial outlay in new milk plant buildings, required to secure complete safety for such plants, would be relatively simple and not burdensome. In older buildings it would require expenditures dependent on the size and complexity of the plant. In the case of plumbing 20 to 25 years old, complete renovation is in order.

The administration of a program for the elimination of such defects presents much greater difficulties than the technical problems. Additional personnel must be thoroughly trained and competent. This will require an intensive training service, since few individuals have had experience with these problems. Careful detailed surveys will be necessary, and recommendations based on the findings must be accurate.

Plans for new plants must be carefully checked and approved before the construction contract for building or equipment is let, and field checked after installation to assure compliance. The work is very definitely a function of the health department and should be under the supervision of a competent public health engineer. When the existing plumbing inspection department is not under the jurisdiction of the health department, close coöperation is essential. The health department should not delegate the responsibility for assuring safe plumbing in milk plants to any other department, for the same reasons that the responsibility for proper milk pasteurizing and cooling equipment is not delegated to another agency.

CONCLUSIONS

A survey of plumbing in 6 milk plants, undertaken to determine whether any condition potentially hazardous to health existed, revealed the following:

1. A total of 210 plumbing defects were found involving 28 different kinds of milk plant equipment.
2. These faulty conditions are due to defective plumbing installations and fixtures, poor design of milk plant equipment, and inexperienced planning of the location and capacities of sewage systems within milk plant buildings.
3. These hazards to health should be eliminated, and in the future supervision of milk plant sanitation should include careful attention to plumbing as well as other features already watched with vigilance.
4. The problems presented by satisfactory control of milk plant plumbing offer no greater technical difficulties than have already been solved in the safe handling and processing of milk and milk products.
5. The responsibility for the administration of the program for correcting existing defects and prevention of future ones should rest with the health department.

Eating Utensil Sanitation*

JAMES G. CUMMING, M.D., Dr.P.H., and N. E. YONGUE
District of Columbia Department of Health, Washington, D. C.

THE object in cleansing eating utensils should be not only cleanliness but also disinfection. It is well recognized that the infective organisms of the respiratory or saliva-borne infections are transferred in the nasal or mouth excretions by way of the air-borne route and by indirect contact through food, hand-to-mouth, or eating utensil transmission. Aside from the relative importance of these several avenues of infection distribution it should be pointed out that the saliva-borne infections as a group, including the pneumonias, tuberculosis, influenza, scarlet fever, measles, etc., are responsible either directly or indirectly for from 25 to 45 per cent of our mortality.

We have the pneumonias of infancy, the communicable diseases of children, tuberculosis of early and middle life, the resultant damaged heart and kidney of advanced middle life, and the pneumonias of the aged. If these as a group are to be brought under control, their avenues of distribution must be blocked, as were those for the typhoid group; in the latter case by public water purification and milk pasteurization. Basically there is no difference between the control of these two groups of disease. The same epidemiological principle applies to both: that the major avenue or avenues of spread must be continuously blocked in order to secure control leading to eradication. Such measures of control must be applied not only during an epidemic emergency, but they must be continuous and permanent. This continuous blocking process applies more particularly to the saliva-borne than to the typhoid group. In the latter group massive transmission means an explosive outbreak, while in the saliva-borne diseases, especially the pneumonias and tuberculosis, the distribution of infection is only potentially dangerous and does not immediately manifest itself.

Prior to the 1918 influenza-pneumonia epidemic, the respiratory group of diseases were regarded as air-borne, and practically all effort in their control was directed at the prevention of nose and mouth spray. It is, however, apparent that if the tubercle bacillus or the pneumococcus were present in the saliva this germ laden saliva could be passed from one person to another through inanimate objects by indirect contact, just as one transfers a culture from one test tube to another by a platinum loop. In short, outside the laboratory the eating utensil may do the work of the platinum loop.

It was in 1917, as a result of observations at Camp Tanforan, Calif., on the faulty methods of mess sanitation that the theory of eating utensil transmission was advanced.[1] This theory was supported by epidemiological and laboratory findings. In an epidemiological study of 66,076 troops it was shown that there was an influenza rate of 51.1 per 1,000 troops among those who had the advantage of

* Read before the Laboratory Section of the American Public Health Association at the Sixty-fourth Annual Meeting in Milwaukee, Wis., October 7, 1935.

collective washing of utensils, while among those who washed their own mess gear in warm water the rate was 252 per 1,000.[2]

In a second field observation among 5,971 troops it was found that the use of boiling water for washing mess gear gave a protection of 85 per cent against the group of saliva-borne infections by blocking distribution through the 5 link chain of transmission.[3] An investigation in two large cities indicated that mechanical washing as contrasted with hand washing of dishes minimized mass indirect contact and afforded a protection of 80 per cent against influenza infection.[4]

Similarly, in public institutions having a population of 252,186 inmates, those protected against influenza by the machine washing of utensils had but one-third as many cases of influenza as those exposed through the hand washing of dishes.[5]

By laboratory procedures it was shown that 99 per cent of the organisms were removed by the machine method of washing, while but 78 per cent were removed by hand washing.[6] Furthermore, in the latter procedure, pathogenic organisms were isolated from both the wash water and from washed utensils.[7] These investigations included the transmission of tuberculosis from not only the wash water of spoons used by open cases in 35 per cent of the trials, but also from the washed spoons in 25 per cent of the trials.[8]

The joining of the 5 link chain of multiple indirect contact transmission was established by passage of *B. prodigiosis* from oral cavity of donor to that of recipient in 34 per cent of the trials.[9]

AVAILABILITY OF CHLORINE IN SOLUTION

During the last two decades the use of chlorine as a gas, as organic chlorine, and as hypochlorite, has found an extended field of usefulness as a disinfectant. Gaseous chlorine has been adapted to the disinfection of public water supplies and swimming pools. More recently, these preparations have been used to a limited extent for the disinfection of beverage glasses and tableware.

The action of chlorine in solution as a disinfectant is generally attributed to its formation of hypochlorous acid. This acid easily breaks down into hydrochloric acid and oxygen, thus being an oxidizing agent. The oxidizing action on bacteria is thought to be explanatory of the disinfectant properties.

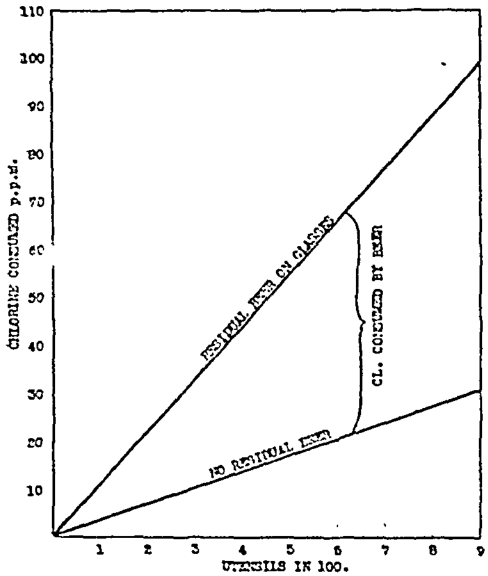
It is evident that the proper alkalinity of the solution for the production of hypochlorous acid is of great importance. This has been shown by Johns (Cf. *Scientific Agriculture,* 14:11, July, 1934) and others. Work must continue, however, to demonstrate the necessity of pH control at high concentrations under practical working conditions such as are maintained in the average restaurant.

The fact that the "available chlorine" does not truly represent the chlorine condition, and, therefore, the germicidal potency of a chlorine solution may be better illustrated by a diagram:

$$\begin{tikzcd} \text{Chlorine compound} \arrow[dr] & Cl_2(HO\,Cl) \arrow[d] & \text{Organic addition products} \arrow[dl] \\ & \text{available chlorine} & \end{tikzcd}$$

In dissolving chloramine T or a hypochlorite, the solution supposedly has available chlorine attached to the parent molecule, chlorine in solution, chlorine as hypochlorous acid, and cer-

CHART I.



WASHING OF BEER GLASSES
Showing consumption of chlorine by residual beer.

tain organic addition products. Ordinarily, we test these solutions by determining the available chlorine which must include chlorine from these various sources. It must be admitted in this connection that hypochlorites, especially sodium hypochlorite, releases all of its chlorine into solution much more readily than chloramine T. A simple experiment was performed to prove this statement. A solution of chloramine T and one of a hypochlorite were prepared, each having 200 parts of available chlorine. Each solution was diluted so as to render 0.3 to 1.0 part of free chlorine. The orthotolidine test was applied to each diluted solution, after adjusting the pH to barely the acid side—using the same amount of reagent in each test. After comparing the standards it was found that in the case of the hypochlorite the results from the orthotolidine test and the U.S.P. potassium-iodide-starch test were the same. While with the chloramine T the orthotolidine test gave about 20 per cent as much available chlorine as did the U.S.P. method. The situation is similar to hydrogen ion concentration and available acidity. Hypochlorites may be likened to highly ionizable acids. It would be expected therefore to obtain disinfectant properties at a lower available chlorine concentration from hypochlorites than from chloramine T.

For practical operation in the field, the available chlorine concentration at which we have a plentiful supply of hypochlorous acid and chlorine in solution is important, also, procedures which might influence the supply of these forms of chlorine in the disinfection of utensils become increasingly important.

In the laboratory the operations can be adjusted to the demands, but in the field practical conditions of oxidation must be provided to insure adequate disinfection.

CHEMICAL DISINFECTION

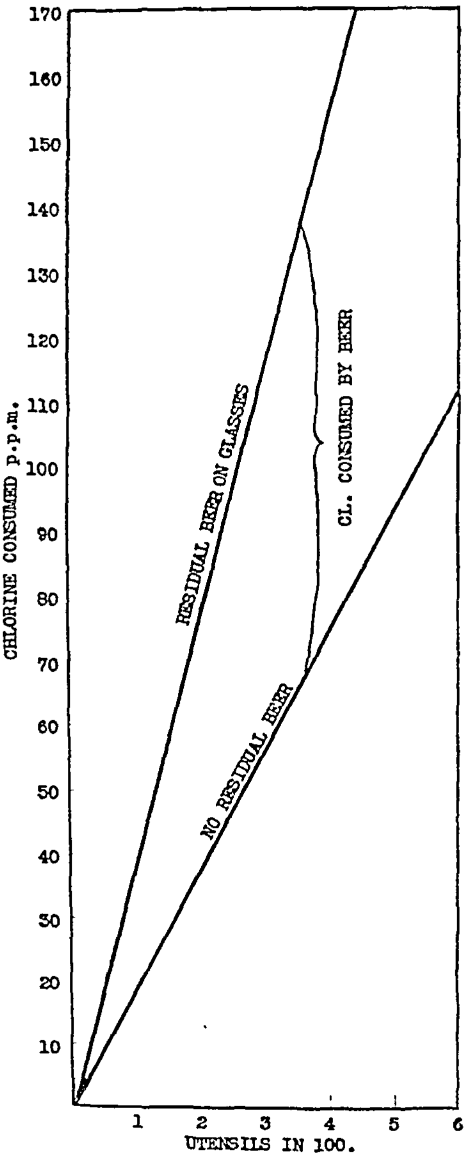
Glasses

While from a public health viewpoint the distribution of disease through beer glasses is of less importance than through eating utensils in public eating places, an extended investigation was carried out to determine, first, the chlorine consumption by residual beer carried directly into the disinfectant solution, and, second, the chlorine consumed by soapy solution carried over by the glasses into the disinfectant.

By the two compartment procedure the glasses with their residual beer were immersed in the chlorine solution for about 2 minutes. They were then rinsed in an overflow compartment of clear water. By this method about 10,000 glasses were treated during a 9 day test period, and hourly samples of the disinfectant were taken to determine the available chlorine. It was found that the chlorine consumed per glass was 0.11 p.p.m. of an organic chlorine preparation.

In contrast with the above experi-

CHART II.



WASHING OF BEER GLASSES
Showing consumption of
chlorine by residual beer.

ment it was found that by using three compartments, in the first, rinsing the glasses in running water, thus removing the residual beer, the chlorine consumption per glass was but 0.034 p.p.m. as shown in Chart I. The residual beer with its organic content consumes about 3 times as much chlorine as when the glasses are previously rinsed.

The residual beer consumes more chlorine per utensil when inorganic chlorine preparations are used than with the organic compounds. In contrast to the above experiment in which chloramine T was used, it was found that the consumption of chlorine in the inorganic form as a result of the addition of residual beer was 0.384 p.p.m. per glass—more than 3 times as much—and that when the glasses were first rinsed the consumption was 0.188 p.p.m. per glass.

Here the importance of the addition of organic matter such as residual beer in the consumption of chlorine is shown. It is apparent that the operation must be closely supervised as to method as well as to the availability of chlorine in the disinfectant solution.

Tableware

In the washing and disinfection of tableware, it was found that the carry-over of residual soapy wash water on the dishes had a decided influence in increasing the consumption of chlorine.

A series of experiments were first run by the three compartment procedure. The first compartment contained soapy wash, the second a hypochlorite solution, and the third clear rinse water. About 3,000 dishes over a 5 day period were washed and disinfected by this method, and at hourly intervals the available chlorine was determined. The consumption of chlorine per utensil was 0.208 p.p.m. or about 20 p.p.m. per hour (Chart III).

In contrast to the above consumption of chlorine, it was found, in a series of tests in which 17,000 dishes were washed and disinfected by the four compartment method which included a rinse of the soapy dishes before immersion in a hypochlorite solution, that the chlorine was consumed at the rate

of only 0.075 p.p.m. per utensil or 10.6 p.p.m. per hour. It will be noted that the organic fatty acids of the soap consumed 0.133 p.p.m. of inorganic chlorine per utensil washed and when not removed by the rinsing process over two times more chlorine was consumed.

In other words, if one were to start with 100 p.p.m., and the residual soapy water on the dishes were added to the chlorine solution, all the chlorine would be consumed in 5 hours; while if the soapy dishes are subjected to a rinse, the disinfectant solution would last 10 hours. Similarly, on the basis of a 100 p.p.m. of available chlorine twice the volume of the solution is needed to meet the requirement when residual soapy water is added.

FIELD BACTERIOLOGICAL INVESTIGATIONS

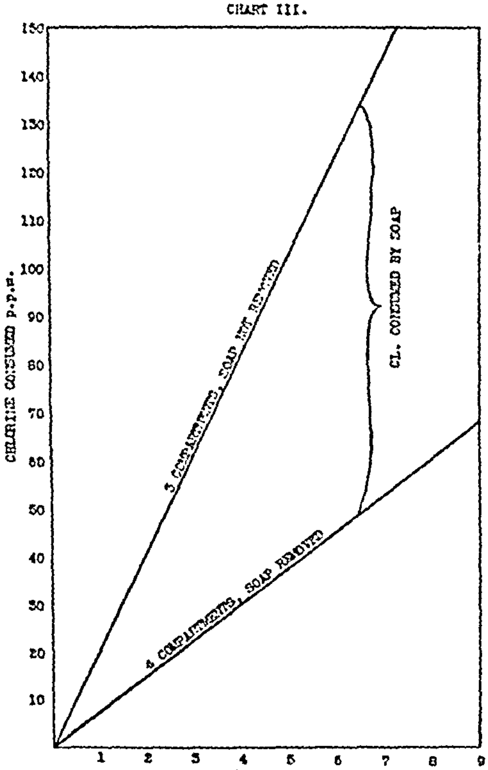
As in our original investigation of the transmission of the saliva-borne diseases, in this work the spoon was used as the bacteriological test utensil. It actually enters the mouth of both donor and recipient, and, because of its large exposed surface area, carries more oral bacteria in the mucus adhering to it than any other utensil. Furthermore, its bacterial load can be determined more easily than that of other utensils. This can be readily done by placing 10 spoons in a pint jar containing 200 c.c. of sterile salt solution immersing only the bowls, shaking for 3 minutes, after which by the plate method the number of bacteria per spoon may be determined. This multiple spoon test for determining cleanliness and disinfection as a standard for all table utensils is simple, accurate, and dependable.

But there is another test of equal importance—it is the bacterial count per c.c. of the wash waters. A soapy solution may remove grease and visible dirt, but at the same time the washing of successive dishes adds to the bacterial count of the wash water until finally the contamination runs so high that the utensils may carry more organisms after, than before they were washed. And then too, when the wash water is heavily contaminated the hands of the operator carry a heavy load of bacteria, and this constitutes a hazard, not only to the operator but to the public as well, for the operator is frequently employed also in the preparation of food.

We then have two control factors: the multiple spoon test, as well as the test of the wash water. Both are important as regulatory factors for the protection of public health. While the work here reported is not final the aim has been toward developing a practical procedure of dish washing which would satisfy the bacterial tests for both the utensils and the wash water.

A number of different procedures were used and while utensils could be

CHART III.



HAND WASHING OF TABLEWARE
Showing consumption of chlorine by residual soap on dishes.

TABLE I

Hours	Soapy Wash Bact. per c.c.	Soapy Rinse Bact. per c.c.	Chlorine Available	Spoons Bact. per Spoon
1st	12,000	8,000	184.3	0
2nd	50,000	20,000	166.6	0
3rd	100,000	60,000	141.8	2
4th	120,000	100,000	88.6	0
5th	250,000	100,000	53.1	2

produced with a satisfactorily low count, the stumbling block to the operations was the high count in the soapy wash water. For instance, as shown in Table I, during a 5 hour run by the four compartment method, the bacterial count of the soapy wash water in compartment 1 at the start was 12,000 per c.c. and at the end 250,000 per c.c. The count of the soapy rinse water in compartment 2 used to free the utensils of soap before immersion in chlorine rose from 8,000 bacteria per c.c. to 100,000 per c.c. The exposure of the utensils in 3, the chlorine compartment, was 5 to 7 minutes. The available chlorine in this run was 185 p.p.m. at the start and 53 at the finish. The object of the clear water rinse compartment 4 is to free the utensils of chlorine odor and taste. This is necessary when the dishes are immediately used after washing, but only when the inorganic compounds are used. By the multiple spoon test the utensils appeared to be satisfactorily disinfected; viable organisms having been found at the end of the 3rd and 5th hours only.

As far as the disinfection of utensils by the multiple spoon test is concerned, Table I presents almost perfect results, but the soapy and rinse waters are highly polluted, a hazard to the public through the operator, who not only washes the dishes but prepares food.

In order to meet the requirement of low bacterial counts in the soapy wash water it was chlorinated, and the chlorine consumption and bacterial counts were determined. Of the many runs by this procedure two are presented: an organic chlorine compound being used in Table II, and an inorganic one in Table III.

While there is a marked difference in the consumption of chlorine in the soapy wash of the two experiments here presented, it is to be pointed out that this is no criterion as to regularity of chlorine consumption in the numerous experiments performed in this series. The tables are selected at random and merely to indicate the system of operation.

In the soapy wash solution the chlorine is consumed by the fatty acid

radicle of the soap and the organic food substances. We have found that there is a wide variation in the chlorine consumption not only by different soaps, but as well by the same soap under different conditions, and presumably different foods in large or small quantities consume variable amounts. Then too there is not only the consumption of chlorine but as well the pH of the solution as affected by the wide variation in the alkalinity of soaps, the pH in turn influencing the germicidal properties of the chlorine.

As shown in Tables II and III, the amount of organic chlorine preparation consumed was only about one-third that of the inorganic preparation, but as previously pointed out, the availability of germicidal chlorine in the field of action is important. This availability of germicidal chlorine has two extremes in the several chlorine preparations: in the organic least available, in the alkaline inorganic most available. The one is not readily consumable, the other easily broken down into its end product oxygen, and immediately available in abundance for quick action.

DISCUSSION

That there is need for a higher standard of eating utensil sanitation in public eating places is indicated by the recent finding that 33 per cent of the organisms remain on the utensils after they are washed (soiled 150,000 and washed 50,000 bacteria per spoon). This percentage represents a cross-section of 46 different restaurants including both the better and poorer types.

If by the soapy water washing method dishes are to be disinfected by either machine or hand washing, they must be subjected to a scalding rinse. At the better places where there is watchful supervision and also an adequacy of scalding water, the disinfection is fairly satisfactory. By the mechanical method at carelessly supervised places the water at the start may be scalding, but by repeated use the temperature drops below the disinfection point. The water then becomes highly contaminated and the dishes carry an increasing load of bacteria. In machines so operated we have found the wash water to carry 300,000 organisms per c.c. and spoons contaminated to the extent of 120,000 bacteria per spoon. This is not the fault of the machine, but it is the entrance into the equation of the personal element. In general, the operators of these machines are unskilled and come largely from a floating population.

In those eating places using mechanical washers where there is insufficient scalding water the disinfection results

would be greatly improved by the use of an inorganic chlorine preparation in the rinse water.

So far, the most satisfactory, but not altogether practical, method for the cleansing and disinfection of utensils by hand is first to rinse off the organic food particles in running hot water, second to wash in an alkali cleanser as tri-sodium phosphate-chlorine solution, and third to immerse in a suitable chlorine solution. When all the dishes of the first set have been placed in the third compartment containing chlorine solution, they should remain there until the second set have reached the second compartment. Thus there is the necessary time exposure in the two disinfecting solutions of 8 to 12 minutes. The water should be maintained at hot hand washing temperature which is about 120° F.

While it is recognized that a chlorine solution will destroy most infectious organisms of the saliva-borne group, the question is still open as to whether or not under practical working conditions it renders the tubercle bacillus non-infectious. This question is of great importance and requires special research.

CONCLUSIONS

1. There is presented a method for determining the efficiency of disinfection of eating utensils by the multiple spoon-bacteriological test.

2. There is pointed out the importance of maintaining a low bacterial count in the wash water, thus securing better disinfection and eliminating a hazard to both dish washer and to the public.

3. The second or rinse water compartment of the mechanical washer may carry a chlorine solution as an additional measure of disinfection.

4. The two compartment procedure for washing beverage glasses, with either soap or alkaline detergent and chlorine in the first, and organic chlorine solution in the second, is satisfactory if the time exposure is sufficient for disinfection purposes. It being understood that the available chlorine in the first be not less than 200 p.p.m. in solution after saturating the organic matter of the soap with chlorine, and a minimum, at no time less than 50 p.p.m.

5. There is presented a procedure for washing dishes by hand, using a sink of three compartments, two of which contain chlorine. It is believed this procedure will give satisfactory disinfection results under practical working conditions. An extended test in the field is, however, necessary to prove its practicability.

Biology of the Oyster in Relation to Sanitation*

PAUL S. GALTSOFF

U. S. Bureau of Fisheries, Washington, D. C.

OWING to several anatomical and physiological features of the oyster, the sanitary control of the oyster industry presents certain difficulties not encountered in the handling and marketing of other perishable sea foods. An understanding of the biology of this mollusk seems indispensable for an intelligent application of the principles of sanitation to this highly specialized branch of the fish industry. The fact that great quantities of oysters are consumed raw and that, excepting its shell, it is eaten in its entirety, makes the question of what constitutes the oyster's food and how it is taken in of great practical importance. Because the mode of feeding of the oyster consists in straining great volumes of water through the gills and ingesting the microscopical suspended material, the purity of the meat is correlated closely with the organism's activity and the character of the water surrounding it.

The feeding of the oyster is controlled by at least 3 sets of organs: gills, mantle, and adductor muscle. The gill may be regarded as the most conspicuous organ of the lamellibranch body which, besides its primary respiratory function, has become a principal organ of feeding, comparable to a very complex sieve capable of filtering a large quantity of water. The synchronous beating of the ciliae covering the surface of the gill, forces the water through the pores into the epibranchial chamber (spaces above the gill lamellae) and into the cloaca. The rate of feeding is therefore entirely dependent upon the efficiency of the ciliated mechanism of the gill. The latter, however, is affected by physical and chemical changes in the outside environment which exert upon it either a stimulating or depressing influence. The filtering capacity varies with size, shape and condition of the organism, but in all the oysters it is controlled by the temperature. At a temperature of about 25° C. an adult oyster may filter as much as 7 liters of water per hour, the rate decreasing with a drop in temperature and at 7° C. activity ceases.

It is obvious that inhibition of ciliary motion results in a deficiency or complete cessation of feeding. This conclusion, made from the results of experiments, was fully corroborated by the author's observations during 3 years (1932–1935) on oysters in Long Island Sound. Stomachs and intestines examined at bi-weekly intervals were completely devoid of food and even no trace of crystalline style was found in the samples taken during the cold season when the temperature of the water was less than 7° C.

* Read at a Joint Session of the Laboratory, Food and Nutrition, and Public Health Engineering Sections of the American Public Health Association at the Sixty-fourth Annual Meeting in Milwaukee, Wis., October 8, 1935.

From the point of view of sanitation it is of interest to determine the efficiency of the oyster gills in removing bacteria from the water. Experiments (Galtsoff, 1928) carried out with oysters placed in water to which a known number of *B. coli* was added, show that only 30 per cent of bacteria are retained by the gills. Apparently these microörganisms are so small that they can pass easily between the cilia and escape back into the water.

The feeding of the oyster is also influenced by the length of time the shells remain open and by the position of the two mantles which, by coming together, may considerably reduce the amount of water sucked in by the gills. Hopkins (1931) has demonstrated in *Ostrea lurida* that it is not so much the existing temperature of the water which determines how long the shell remains open as it is the changes in temperature which control the behavior of the adductor muscle, and are therefore of far greater importance. Falling temperature causes the shells to close, while a rise in temperature is followed by opening. The length of time which oysters remain open depends upon several factors and varies in different localities. From the point of view of sanitary control it is of interest to mention that *Ostrea virginica* may slightly open its shell at 4–5° C. when no current is produced by the gills and consequently no food is found in the intestinal tract.

The oyster possesses a well developed chemical sense which permits the organism to react to changes in the water and detect the presence of small amounts of irritating substances. When a polluting substance is present the oyster protects itself by closing the valves and reducing the number of hours of feeding. Should these conditions prevail for a long time, growth is retarded, the flesh becomes emaciated, and increased mortality ensues. Investigations carried out on the effects of pulp mill pollution (Hopkins, Galtsoff, and McMillan, 1931) showed that death occurred more quickly among oysters which kept their valves open for a longer period of time, those surviving longer which considerably reduced the daily average number of hours during which their shells remained open.

The nutritive value of the oyster meat varies with the seasons and is influenced by the conditions under which it grows. From the nutritional point of view the quality of the oyster is determined by the per cent of solids, glycogen, mineral salts, and vitamin content of the meat. Only the first two factors have been subject to systematic investigation. Normally oyster meat contains about 80 per cent of water, being however, subject to wide fluctuations. Under certain conditions, it is rather difficult to establish a definite standard. Present regulations designed to prevent adulteration forbid putting oysters in water of lower salinity than that in which they were grown. Oysters are very tolerant of changes in salinity. They may thrive as well in water having about 10 parts of salts per 1,000 as in that with salinity ranging between 22 and 27. Moreover, the water content of the meat may vary independently of changes in salinity of the surrounding water. The author's observations show that the water content of oyster meats may increase from 80 to 88 per cent immediately following the shedding of eggs and sperm. As a rule oysters become watery after spawning although the salinity remains constant.

Early in the fall oysters begin to store glycogen, the content of which may reach as high as 12–14 per cent (fresh basis). This process is accompanied by an increase in solids and a corresponding decrease of water in the tissues. At this time oysters have

the highest nutritive value. With the onset of cold weather feeding ceases, though the glycogen content remains on a high level throughout the winter. This indicates that all the physiological activities are greatly reduced and that during the hibernating period the organism draws but little on the supplies stored in its tissues. It is remarkable that in spite of the complete cessation of feeding the growth of shell both in length and weight continues.

There is no information regarding the seasonal fluctuations in the contents of heavy metals and vitamins in oyster tissues, though there are sufficient data to show the existence of a definite correlation between the iron and copper content and their geographical distribution (Galtsoff, 1934). In general, oysters from the North Atlantic are poor in iron and rich in copper, while the reverse is true for the South Atlantic and Gulf States, the variation occurring gradually as we proceed along the coast from Rhode Island to Florida. This suggests that the observed changes are not incidental but may be due to differences in the chemical composition of water. Unfortunately our knowledge regarding the iron and copper metabolism in the oyster is too incomplete to justify further speculation regarding the significance of the observed facts.

An understanding of the salient biological features of the oyster may be useful to the public health officer in outlining and executing an efficient sanitary control of the oyster industry. One must bear in mind that the oyster is readily affected by changes in environment, and easily adapts itself to new conditions. In this respect it differs from other sea food and presents more difficulties from the point of view of sanitation.

The Lag in Education

EVEN the more magnificent scientific discoveries, especially those of recent years, have not penetrated into our general education, and are entirely disregarded in most discussions of social problems. And yet an imposing accumulation of critical information of wide bearing is at our disposal which might become an active factor in the readjustment of the troubled relations of man were it possible to overcome the obstacles to its general dissemination and acceptance.—James Harvey Robinson, *Humanizing of Knowledge*, 1924.

A Rapid Slide Test for the Serological Diagnosis of Typhoid and Paratyphoid Fevers*

HENRY WELCH, Ph.D., and FRIEND LEE MICKLE, F.A.P.H.A.

Research Microbiologist, and Director, Bureau of Laboratories, State Department of Health, Hartford, Conn.

ONE of us with Stuart [1] has described a rapid slide test using concentrated antigens with undiluted sera for the diagnosis of typhoid and paratyphoid fevers. The method proposed follows in general the Huddleson technic [2] for the diagnosis of Brucella infection, the efficiency and accuracy of which have been demonstrated by Lienhardt and Kitselman,[3] Palmer and Baker,[4] and Welch and Mickle.[5] The slide test for the diagnosis of typhoid and paratyphoid fevers makes use of 4 antigens: an alcohol treated *Eberthella typhosa* 'O', *Eberthella typhosa* 'H', *Salmonella paratyphi*, and *Salmonella schottmuelleri*. The antigens are about the consistency of thin cream and are prepared by growing large quantities of organisms on agar in Blake bottles and washing the growth off with concentrated formolized salt solution. All antigens are standardized by titration against known positive and negative sera the titers of which have been previously determined by a standard tube test technic. The test takes approximately 4 minutes to complete. The rapidity and ease with which it may be carried out routinely seemed to us to be an important factor in public health laboratories where speed and accuracy in reporting results to physicians are necessary. In hospitals where an early exclusion of typhoid in certain undiagnosed cases is often important, the rapid slide test should be invaluable.

It has become increasingly evident that some type of 'O' antigen should be included in the routine Widal test to obtain the most accurate interpretation of the agglutinins that are found in cases of suspected enteric disease. In the New York State [6] and Michigan [7] Departments of Health the value of the use of the 'O' type of antigen as well as the 'H' has been definitely shown. The investigations of Gardner,[8] Smith,[9] Craigie,[10] Wyllie,[11] Bole,[12] and others demonstrate the relationship of the 'O' and 'H' agglutinins in sera to vaccination and infection and further emphasize the importance of the 'O' agglutinin in diagnosis.

The method of preparation of our alcohol treated antigen (*E. typhosa* 'O') has been simplified. The method reported was as follows [1]:

Eberthella Typhosa Somatic 'O'—The same strain used in preparation of the flagel-

---

* Read before the Laboratory Section of the American Public Health Association at the Sixty-fourth Annual Meeting in Milwaukee, Wis., October 7, 1935.

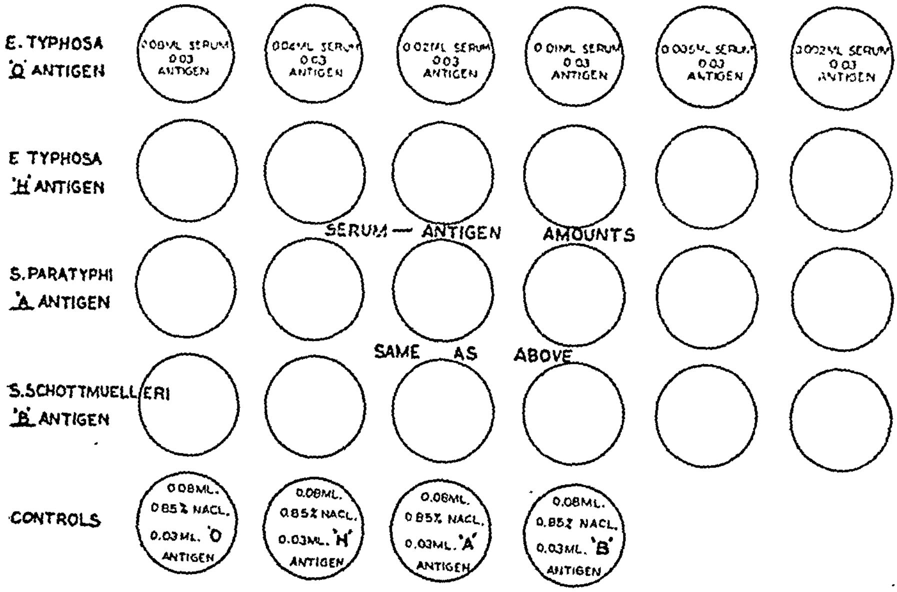
late (HO) antigen is used in making the 'O' antigen. The organisms are grown for 48 hours at 37° C. rather than for 24 hours and are washed from the surface of the agar with 12 per cent NaCl rather than with the formolized salt solution. After centrifugation the supernatant fluid is discarded and the packed bacterial cells are pooled using just sufficient 0.85 per cent salt solution for transfer purposes. This concentrated suspension is placed in a large flask and 15–20 volumes of 95 per cent alcohol is added, the flask shaken vigorously for 10 minutes and incubated at 37° C. for 24 hours. At the end of the incubation period the antigen appears as a flocculent white mass from which considerable of the alcohol may be siphoned and discarded. The remaining alcohol is removed by centrifugation. About 5–7 ml. of 12 per cent salt is added for each 1 ml. of packed bacterial cells and the concentrated suspension is ready for titration.

Instead of centrifugation to get rid of the supernatant fluid, after the organisms have been washed from the agar with 12 per cent formolized salt solution and pooled, 3 volumes of alcohol are added directly to the salt solution suspension of organisms. The flask is shaken vigorously for 10 minutes and incubated at 37° C. for 24 hours. From this point on the preparation of the 'O' antigen follows the original method. This modification saves 1 centrifugation without apparently affecting the efficiency of the final product.

Since our publication,[1] 1,100 sera have been studied with the rapid slide method, and the results compared with our standard tube test technic. The latter test makes use of live organisms as an antigen for the *Eberthella typhosa* 'H', *Salmonella paratyphi*, *Salmonella schottmuelleri* and an alcohol treated antigen for the *Eberthella typhosa* 'O'. All antigens are made to correspond to a turbidity of 6.9 on the Gates[13] apparatus. The serum is diluted 1:10 through 1:320 in a definite sequence and 0.5 ml. of antigen added to each dilution making the final dilutions 1:20 through 1:640. The tube tests are incubated at 52°–55° C. for 3 hours, followed by refrigeration over night. Final readings are made the following day.

FIGURE I

Showing Serum-Antigen Amounts Used in the Slide Test



METHOD

In the routine diagnostic slide test the patient's serum is pipetted onto a 5″ x 7″ glass slide in the following amounts: 0.08, 0.04, 0.02, 0.01, 0.005, and 0.002 ml. in the four rows of rings as shown in Figure I, using a Kahn pipette (0.2 ml. graduated in thousandths). In the fifth row (used only for the first test each day) 0.08 ml. of 0.85 per cent salt solution is added to each of the four rings for controls on each of the four antigens. A drop of 'O' antigen is added to each of the serum amounts in the first row and to the first ring in the fifth row. Similarly, a drop of 'H' antigen is added to each of the serum amounts in the second row and to the second ring in the fifth row. *S. paratyphi* is added to the third row and *S. schottmuelleri* to the fourth row, each with the appropriate controls in the third and fourth rings respectively in the fifth row. The above serum-antigen mixtures in each row correspond to dilutions of 1:20 through 1:640 in the tube test. All antigens are shaken gently but well before using. Each row of serum-antigen mixture is thoroughly mixed with a separate toothpick or applicator starting with the smallest amount (0.002 ml.) of serum and working from right to left. After mixing, the glass slide is gently rocked back and forth 15–20 times and the degree of clumping estimated. The type of agglutination obtained with the 'O' antigen does not correspond to the typical small flaking or granular agglutination obtained in the tube test, and hence 'O' and 'H' agglutination cannot be differentiated by appearance. This is no disadvantage since both types of antigens are used.

RESULTS

Of the 1,100 sera tested by both the slide and tube methods, 400 were sent to these laboratories for the Wassermann test, 200 of which were tested with the regular tube test technic and 200 by the New York State method. The results were compared with those obtained with the slide test on all 400 sera.* The results are given in Table I.

Since the Connecticut tube test technic did not make use of an 'O' antigen at the time this series of tests was begun, but used only a living, motile culture, the New York State 'O' antigen was used in testing all 400 sera listed in Table I. It will be noted that the percentage of reactions obtained with the first 200 sera (when using the New York State 'O' antigen with the Connecticut technic) were quite comparable with the percentage for the second 200 (where the New York State technic was followed), 12.6 per cent of the sera showing reactions in the first 200 sera and 15.5 per cent in the second 200. From an inspection of Table I it will be seen that in all instances with the exception of *S. paratyphi* 'A' antigen the slide tests showed a lower percentage of reactions than did the Connecticut tube test. This was particularly true in the case of the 'O' antigen. On the other hand, when compared with the New York State tube test a greater percentage of reactions was obtained with the slide 'H' antigen than with the New York State 'H'. However, the slide 'O' antigen again showed considerably fewer reactions when compared with the New York State tube test 'O'. It would appear that the slide test is slightly more specific than the Connecticut tube test method, and this would appear also to be true with the slide 'O' antigen when compared with the New York State tube test 'O', although the slide 'H' is definitely less specific when compared with the New York State tube test 'H' antigen. The degree of agglutination obtained with the New York State 'H' antigen was greater than the degree of agglutination obtained with the 'H' slide antigen in most instances.

Seven hundred * of the sera used to

* The New York 'H' and 'O' antigens used were kindly furnished by the New York State Laboratories at Albany, N. Y.

* The authors are indebted to Dr. M. H. McCrady, Montreal, Que., to Dr. J. G. McAlpine, Montgomery, Ala., and to Esther Brintzenhoff, Providence, R. I., who kindly furnished us with some of the sera used in these studies.

	Slide Test	42.5	8.5	....	....

* The New York antigens were kindly furnished by the Division of Laboratories and Research of the New York State Department of Health.

[1] Using New York State antigen with Connecticut technic.

[2] As nearly as possible the New York State method was followed throughout.

make comparisons between the tube and slide technics were sera sent for the routine Widal test. One hundred, or 14.4 per cent, were from known cases of typhoid or paratyphoid fevers demonstrated clinically or by isolation of the etiological agent. Fifty, or 7.1 per cent, were from individuals known to have had vaccine. Two hundred and sixty sera, or 37.1 per cent, showed partial reactions by one or both tests and 290, or 41.4 per cent, showed no reactions with either test.

In Table II are summarized the results obtained in a comparison of the tube and slide tests on sera from 100 cases, 73 of which were cases of typhoid fever and 27 cases of paratyphoid B. With the typhoid sera the slide test gave fewer negative results with both the 'O' and 'H' antigens than the tube test with these antigens. This greater degree of sensitivity of the slide test is reflected in the cross-reactions obtained with the 'A' and 'B' antigens since the slide test showed fewer completely negative results than did the tube test with these antigens. The cross-reactions obtained with the 'A' and 'B' antigens in the slide test were usually slight reactions in the first 2 dilutions. This is shown in the higher percentages of reactions obtained with the 'A' and 'B' antigens in the 1:20 and 1:40 dilutions. A higher percentage of reactions was obtained in the 1:320 dilution with the tube 'O' antigen (62.5 per cent) than with the slide 'O' antigen (47.9 per cent). On the other hand, the reverse of this is true with the 'H' antigens (tube test 42.5 per cent and slide test 66.6 per cent).

With the sera from 27 cases of paratyphoid B (Table II) both tests failed to show agglutination with the 'B' antigen in 11.1 per cent of the cases. A diagnosis of these cases was made by isolation of the organism. Cross-agglutinations with the 'O' antigen in the slide test were obtained in the same percentage (59.3 per cent) of cases as with the 'H'. Fewer cross-reactions with the 'O' and 'H' antigens were obtained in the tube test ('O' 23.8 per cent; 'H' 37.0 per cent). This was not true with 'A' antigens since the tube 'A' showed reactions in 44.5 per cent of the paratyphoid B cases, whereas the slide 'A' antigen showed cross-reactions in only 25.9 per cent. A higher percentage of reactions was obtained in the 1:320 dilution with the slide 'B' antigen than with the tube 'B' antigen in known paratyphoid B cases. In general, the results obtained on the sera from the paratyphoid cases are similar to those obtained on the sera from the typhoid cases (Table II).

In Table III are given the results obtained on 50 sera from known vac-

Slide B	11.1	0	11.1	7.4	7.4	63.0

cinated individuals. The 'H', 'A', and 'B' agglutinins predominated in this vaccinated group although some reaction was obtained with the slide 'O' antigen in 40 per cent of these sera and with the tube 'O' antigen in 44.3 per cent. It will be noted in connection with this that 4 per cent (2 sera) showed a reaction in the 1:320 dilution in the 'O' antigen of the slide test. These sera were obtained from recently vaccinated individuals, which probably accounts for the high titered 'O' agglutination. In the older vaccinated individuals 'O' agglutinins rarely appeared and when present were found only in low dilutions. The percentage of reactions obtained with the 'O' antigen in the vaccinated group is slightly higher than that reported by

Bole.[12] It would appear from the results obtained in the vaccinated group that the use of all 4 antigens (O, H, A, and B) in the Widal test is extremely helpful in separating the vaccinated individuals from those with known typhoid fever. In general, the results obtained with the tube test and slide tests in the vaccinated group are comparable, although, with the exception of the 'O' antigen, a greater degree of sensitivity was demonstrated with the slide test.

Partial reactions were obtained by one or both tests in 260, or 37.1 per cent of the 700 sera examined. These reactions were usually ++, +, or ± results in the 1:20, 1:40 or 1:80 dilutions although occasionally reactions were obtained in higher dilutions. Twenty-nine sera in this group showed slight reactions in the slide test with no reaction in the tube test, and 47 showed reactions in the tube test which were negative in the slide test. The remaining 184 sera in the questionable group gave partial reactions with one or more of the antigens in both tests. Since in none of the individuals, from which these 260 sera were obtained, was it possible to demonstrate typhoid or paratyphoid fever it would appear that the slide test was slightly more specific. From the results obtained by both tube and slide tests with these questionable sera it appeared that vaccine had been administered previously to some individuals although no definite history was obtained.

The remaining 290, or 41.4 per cent of the 700 sera, received for the Widal examination gave complete negative results with both tests.

DISCUSSION

The large amount of work that has been done in recent years on the standardization of the Widal test and the interpretation of results has made it evident that the use of an 'O' antigen as well as an 'H' is necessary for the serological analysis of a suspected serum. However, even though an 'O' antigen is used, the widespread inoculation with typhoid-paratyphoid vaccine as well as the number of cases of previous enteric infection, both of which stimulate the production of agglutinins for the typhoid-paratyphoid group of organisms, lowers the specificity of the Widal test regardless of the method. No Widal test is infallible and it is not likely that any will be developed that will lower the validity of the isolation of the etiological agent. Although in some cases of typhoid and paratyphoid fevers isolation of the causative organism is made several days before agglutinins are demonstrated in the serum of the patient, in a large number of cases it is not, and agglutination tests are necessary. The value of the Widal test is dependent upon the standardization and maintenance of antigens that will give consistent results.

In the development of the slide test considerable emphasis has been placed upon the preparation of antigens which will give consistent results over several months. The standard tube test, used in these laboratories for several years, although ordinarily giving consistent results, requires considerable work to maintain smooth cultures and antigens which will not vary in their reactions. It has been necessary in using this method to standardize antigens daily (living cultures) and to check organisms for smoothness every 3 weeks. This standard tube test method was shown to be the most efficient when compared with 5 others by Moore.[14] The slide test antigens were standardized as nearly as possible against the antigens used in our tube test.

In general, in the study of 1,100 sera, the results obtained with the slide test compared very favorably with the results obtained with the standard tube

test. The slight differences in the specificity and sensitivity do not appear to be significant. In known cases of typhoid fever the slide test showed fewer complete negative results with the 'O' and 'H' antigens while in the 23 cases of paratyphoid B reported both the slide and the tube test showed exactly the same percentage of negative results. In these cases of paratyphoid B the organism was isolated early in the course of the disease before agglutinins could be demonstrated.

In the investigation of the rapid slide test our main interest has been to develop a test which would give us as consistent results as our standard tube test. We feel that this result has been realized with the technic presented, and that a marked saving in time, glassware, and material has been obtained. The slide antigens give consistent results for at least 5 to 6 months, which is a distinct advantage over our tube test method which requires frequent time consuming standardization. The fact that the slide test results on a serum may be obtained within a few minutes after it is received in the laboratory is a distinct advantage over the tube test technic which usually requires 15–24 hours to complete. We have found also that it is possible to standardize the slide test antigens within reasonable limits to other tube test technics. This should be an advantage to laboratories that are completely satisfied with their tube test technic, but desire to obtain results on suspected sera in a shorter interval of time.

In a comparison of the New York State tube test technic with the slide test on 200 Wassermann sera excellent agreement was obtained in spite of the fact that the slide test antigens were not standardized against the New York State antigens. Similar results were obtained with the 80 sera kindly sent to us by Dr. McCrady who had used the Dreyer technic in the analysis of these. In this group of 80 sera only 3 showed disagreement in results, and in 2 of these 3 the results obtained were sufficiently clear-cut in both tests to establish a diagnosis.

It would appear to us that the slide test proposed should be an excellent one for routine diagnostic purposes in public health laboratories where speed and accuracy in reporting results to the physicians are necessary, as well as in hospital laboratories where exclusion of typhoid in certain undiagnosed fevers is often important.

SUMMARY

A rapid slide test for the diagnosis of typhoid and paratyphoid fevers is presented which requires approximately 4 minutes to complete. The results obtained in a study of 1,100 sera indicate that the slide test is at least as sensitive and specific as the tube tests with which it was compared. The stability of the antigens used, the speed and accuracy with which a serum may be analyzed by this method, and the consistency of the results obtained, indicate that the test should be an excellent one for use in public health laboratories and in hospitals where an early exclusion of typhoid fever in certain undiagnosed cases is often important.

Aluminum in Food

PROPAGANDA as to possible dangers resulting from the use of aluminum cooking vessels is so persistent that one suspects ulterior motives in its background. The problem has been investigated at various times, and in the presence of a renewed criticism of the widespread employment of aluminum vessels another recent study of the subject has appeared under the auspices of the British Ministry of Health. (Monier-Williams, G. W.—*Aluminum in Food*, Report 78 on Public Health and Medical Subjects, London, Ministry of Health, 1935.) The accurate determination of aluminum in food and biologic material, according to Monier-Williams, who wrote the report, is a difficult matter. The amount usually present is small and cannot easily be separated completely from iron and other metals. The method that has finally been adopted depends on the precipitation by 8-hydroxyquinoline and, although considerably longer than some of the colorimetric methods, has the advantages that it is applicable over a wide range of aluminum content and that the aluminum is obtained in a form in which it can be weighed or titrated. The figures for the amount of metal taken up by food from aluminum vessels vary considerably, owing to different conditions of experiment. Distilled water, whether hot or cold, has almost no action. Hard waters, however, corrode aluminum slightly and the same is true of organic acids. Aluminum is readily acted on by alkalis, and cooking utensils are therefore liable to be damaged if cleaned too often with soda. The problem of whether or not aluminum is injurious in moderate doses involves a number of different questions. It is probable that a considerable proportion taken into the stomach is soluble. Whether it can diffuse through the walls of the intestinal tract and get into the blood is a matter of further controversy, and at present judgment on this matter must be suspended. Aluminum salts in doses that are not unreasonably high have been shown to have some action on digestive processes.

There is no convincing evidence, however, that aluminum in the amounts in which it is likely to be consumed as a result of the use of aluminum utensils has a harmful effect on the ordinary consumer.—*J.A.M.A.*, Jan. 18, 1936, p. 218.

An Epidemic of Dengue*

HENRY HANSON, M.D., F.A.P.H.A.

State Health Officer, Jacksonville, Fla.

THERE has been some general information about the epidemiology of dengue for a considerable time, but it is only since the epoch making work of Siler, Hall, and Hitchens [1] that we have had exact information regarding the transmission of the disease. The first accurate descriptions of dengue were by Brylon of Java in 1779, and by Benjamin Rush of Philadelphia in 1780.[2] Reference to transmission by mosquitoes was made by Graham, of Beirut, Syria, in 1903.[3] For a long time it was thought that some such variety of culex as the *quinquefasciatus* or *C. fatigans* was the principal transmitter, a point which was not cleared up until the researches of Siler and his coworkers in the Philippines, and later confirmed by Simmons, St. John, and Reynolds.[4]

With the above facts established, the control of an epidemic is made possible through a systematic anti-larval campaign, *i.e.*, preventing the full development of mosquito larvae of the species which has been proved to be a carrier of the disease. Inasmuch as Siler's work definitely incriminated the *Aëdes aegypti* (formerly known as the *Stegomyia fasciata*), a mosquito which is in this country the only known carrier of yellow fever, the control will consist of the same procedure as employed in control and suppression of an outbreak of yellow fever.

There are some points wherein the two diseases differ: Mortality in dengue is very low, by some given as from 1 in 5,000 to 1 in 1,000, while in yellow fever 10 per cent has been regarded as a low death rate. Among my series of 478 cases on the coast of Peru on which history was available,[5] the mortality was 40 to 41 per cent. Among white Europeans in West Africa it seemed to run as high as 66 per cent. The second important point of difference lies in a lasting immunity following an attack of yellow fever, while in dengue there appears to be a short immunity, and not of uniform occurrence at that. Immunization by an attack becomes an important item in shaping a campaign for the control of an epidemic. It will make a considerable difference in the required critical index of mosquito production. In yellow fever the critical index may be said to be the percentage of mosquito production which permits the propagation of the disease. The index will vary according to the number of immunes in the population, *i.e.*, the infected mosquitoes may feed on immunes and die before taking another blood meal. The greater the number of immunes in a population, the easier it will be to stop the epidemic. Under such conditions the epidemic will cease while the mosquito incidence is still high. If there are few or practically no immunes, the mosquito production must be brought to a very low level. Owing to the low immunity production in dengue the mosquito incidence, *i.e.*, the production

* Read before the Epidemiological Section of the American Public Health Association at the Sixty-fourth Annual Meeting in Milwaukee, Wis., October 7, 1935.

index, would have to be brought close to a relative zero.

An epidemic of dengue can best be discussed by referring to the sequence of events in a locality where such an epidemic has occurred. When we received word from Dr. George MacDonnell, Health Officer of Miami,[6] that he had found a number of cases of dengue, we at once thought of the possibility of its spreading to other points in the state, and eventually throughout the whole South.

It appears that epidemics of dengue occur periodically at intervals of from 8 to 10 or 12 years. This is rather interesting when one considers the evanescent nature of the immunity conferred. In the past there had never been a systematic anti-aegypti campaign for the control of dengue. Our effort in Florida in 1934, in so far as I know, was the first attempt to control and wipe out an epidemic of dengue by anti-larval methods. Dr. MacDonnell put on a force of 50 inspectors for the city of Miami, and also exercised some supervision of the suburban areas. The writer, with the assistance of Dr. T. H. D. Griffitts, of the U. S. Public Health Service, made a tour of the principal cities in the southern part of the state, urging the adoption of a clean-up campaign to stop the breeding of the *A. aegypti* as the surest safeguard against the appearance of dengue in the community. A town or city which does not have adult *aegypti* cannot have dengue. I was anxious to demonstrate that an epidemic of this nature could be confined to the state where it originated. To do so required prompt and energetic measures. One of the difficulties encountered was the lack of experienced personnel. One must learn the habits of the mosquito before effective inspection can be made. In many places relief labor was relied upon, as in Tampa, where in spite of several weeks of inspection many new cases of dengue were reported. On checking the areas which had been reported free of *aegypti* by the relief workers, we found the breeding profuse, and many adult mosquitoes on the wing. It became necessary to send in several trained inspectors to supervise the work and to train personnel, in order to insure a prompt reduction in *aegypti* production.

I wish again to call attention to the need for a low index of breeding or production of *aegypti* before one can hope to control an epidemic of dengue. Our work in Florida last year served as a demonstration of what must be done to control an epidemic of a disease which is propagated by container-born mosquitoes. The *aegypti* is a species which in nature breeds only in artificial containers, and then preferably near or within human habitation.

The appearance of dengue also served to awaken the people to a realization of the universal distribution of the vector of both dengue and yellow fever. The belief had been general that there were not enough *aegypti* on the wing to make possible the spread of an epidemic of yellow fever, and that should some cases appear we would be able to stop the epidemic promptly. Dengue control was further complicated by the irregularity with which inspection personnel could be obtained. The majority of communities used relief labor for this purpose, and the almost daily shifting of personnel resulted in a surplus of untrained as well as uninterested labor. The results of such inexpert inspection were often *nil*, or worse, in that the authorities then had a false sense of security. Checking the breeding in reportedly inspected areas, we found larvae and pupae galore.

It was difficult to determine the extent of the epidemic. We did not have a sufficient number of trained physicians to visit all the reported cases. Most of the mild cases were never seen by a physician; hence the ratio of cases to

the actual number reported was thought to be about 10 to 1. On the other hand, the fact that dengue had been proved to exist caused many questionable cases to be reported as dengue which otherwise would have been reported as something else. It is also true that the announcement of an unusual disease will sometimes result in enough reported cases to simulate an epidemic, if there is not an adequate medical force to investigate and correct the reports. Griffitts [7] shows a distribution of the towns reporting dengue. Many of these reported only 1 case, and the probability is that in some instances there was no dengue, while in others there may have been the estimated 10 cases for each 1 reported. In Griffitts's analysis of the ages of the sick it was found that all age periods from 1 year up to 70 were represented. This is as it should be in a disease which does not confer a lasting immunity. In contrast I can cite the incidence of yellow fever in the Peruvian epidemics of 1918 to 1921,[5] in which most of the cases occurred in individuals under 30 years of age, among those who were native to the territory affected. It was found that those older, who contracted yellow fever, had come into the area after the last epidemic, which occurred from about 1895 to 1897.

In a study of immunity in dengue by Sharp and Hollar [8] the conclusions point to a transitory immunity, and to the fact that it does not regularly follow an attack. Suggestions are also to the effect that there may be a strain specificity. The duration of immunity is thought to vary from 1 to 4 years.

In Greece the mortality was reported to be high, but a close analysis indicated that it occurred among elderly people and those with chronic disease. In such instances it is a question whether the mortality should be charged to dengue other than as a contributory factor.

CONCLUSION

The recent epidemic in Florida is thought to be the first in which a serious attempt was made to control dengue through anti-larval methods. If no effort had been made it is believed that there would have been a general epidemic over the entire South like that of 1922.

In controlling dengue by anti-larval work it will require a lower index of breeding than it does to control an epidemic of yellow fever.

Immunity in dengue is irregular while in yellow fever it appears to be universal and permanent. Herein lies an important factor in the mosquito control of the two diseases.

Trained personnel with a knowledge of the habits of mosquitoes is necessary for the control of any mosquito-borne disease, and especially for the control of dengue.

While it is the same mosquito which carries both yellow fever and dengue, it requires a more intensified destruction of breeding places to control and wipe out an epidemic of dengue than it does to wipe out an epidemic of yellow fever.

Detection and Significance of Escherichia coli in Commercial Fish and Fillets*

FRANCIS P. GRIFFITHS, PH.D., AND JAMES E. FULLER, PH.D.

Junior Bacteriologist, U. S. Bureau of Fisheries; and Assistant Research Professor, Massachusetts State College Experiment Station, Amherst, Mass.

THE use of marine fish as food has increased tremendously in recent years. Better distribution facilities, increased advertising, and the general recognition that fish is a nutritious food and an important source of essential minerals, have all contributed toward popularizing fishery products as a regular part of the diet.

Changes in the methods of handling and marketing certain marine fish have occurred coincidently with their increased use. Formerly very little fresh fish was sold except "in the round," *i.e.*, as caught, or else eviscerated. A large proportion of the catch of cod, haddock, and hake was eviscerated, split, salted, dried, and sold as dried salt fish or "fish flakes."

Today a large proportion of the fresh or frozen fish is "packaged," that is, it is sold prepared either as fillets or in other ready-to-use form. According to the statistics of the U. S. Bureau of Fisheries,[1] 49,000,000 lb. of fish, chiefly haddock, valued at about $5,500,000, were sold as fresh or frozen fillets in 1933. The fish are usually caught by otter trawls, hand lines, or purse seines, and are eviscerated on the vessel, packed in ice in bins or cribs, and brought to port. After being sold to commercial dealers the fish are washed, scaled, and filleted. The fillets are washed, usually in a salt brine, wrapped in parchment, and those sold fresh are packed in 10 and 25 lb. quantities in tin boxes, which in turn are packed in ice for retail shipment.

So much handling, between catching and purchase by the consumer, naturally increases the chances of contamination and the rapidity of subsequent spoilage, particularly in fillet form.

Laboratory tests for the sanitary quality of various food products have come into wide use. However, the bacteriological examination of marine fish has not become common and there are no standard methods for such examination.

There are two possible standards on which the quality of market fish might be based; one the total bacterial count on the fish flesh, and the other the detection of some specific type of bacteria, such as *Escherichia coli*, sanitary significance of which could be interpreted.

REVIEW OF LITERATURE

The majority of investigators agree that the flesh of live fish and of freshly

* Read before the Food and Nutrition Section of the American Public Health Association at the Sixty-fourth Annual Meeting in Milwaukee, Wis., October 10, 1935.

caught fish is sterile. Hunter[2] and Fellers[3] found that the digestive tract and flesh of migrating salmon was usually sterile. Proctor and Nickerson,[4] in examining the flesh of 96 fish, frozen with dry ice immediately upon being caught, and examined upon reaching the laboratory, reported all except one sample to be sterile.

The slime of fish is not sterile and, after the death of the fish, serves as an excellent medium for the rapid multiplication of bacteria. Gee[5] made isolations from slime of live haddock and found numerous organisms. Stewart[6] examined the slime content of 22 haddock. Of the 247 cultures isolated, 140 corresponded in general characteristics with the genus Achromobacter. Organisms of the mammalian intestinal type were not found, and only 4 cultures belonging to the genus Aerobacter were isolated.

All investigators agree that bacterial invasion of the flesh occurs soon after the death of the fish. The number of organisms present and the rate of spoilage depend on several factors, temperature of storage and carefulness of handling probably being most important. Griffiths and Stansby[7] in studying the correlation between chemical and bacterial tests for freshness of fish flesh found that with market haddock, caught from 4 to 10 days, the bacterial count was between 10,000 and 100,000 per gm., while counts of 500,000 to 1,000,000 were typical of very stale and unmarketable fish. The maximum period during which haddock stored in ice could be kept in an edible condition was between 16 and 21 days. Fillets, because of their greater initial contamination, spoil more rapidly.

Because of the public health significance of *Escherichia coli* in water and foods as an indication of potentially dangerous contamination, the possibility of its occurrence in the intestinal tract of lower animals and of fish has been investigated. Gibbons[8] in a review of literature and as the result of his own investigations concluded:

> *E. coli, E. communior* and *A. aerogenes* are not normal inhabitants of the intestinal tract of marine fishes. Representatives of the genera Escherichia and Aerobacter may be found in marine fishes, but they seldom occur in fish taken some distance off-shore. The fecal forms are particularly rare, except in fish taken near shore or in contaminated waters.

Griffiths[9] did not find fecal *Escherichia coli* in the slime or flesh of fresh haddock, but found typical fecal *E. coli* on 5 commercial fillets examined. Hunter[10] considered the presence of *E. coli* in cooked crab meat an indication of contamination due to faulty handling.

PURPOSE OF THE PRESENT INVESTIGATION

It was the purpose of the present study to investigate the occurrence of bacteria of the coli-aerogenes group on market fillets and whole fish, and to determine the proportion of these organisms which could be identified as fecal (mammalian) *Escherichia coli.*

METHOD OF INVESTIGATION

Fish and fillets were purchased from retail stores. The fish were carefully filleted in the laboratory and both the laboratory and the store fillets were skinned. The flesh was then ground twice through sterile meat grinders into sterile pans, and 5 gm. portions were weighed into dilution bottles containing 99 ml. of sterile water for a 5 to 100 dilution. After being in a mechanical shaker for 10 minutes, 10 ml. were added to 90 ml. of sterile water to make a 5 to 1,000 dilution. Five tubes of lactose peptone brilliant green bile broth were inoculated with 0.5 gm. portions of the ground fish, 5 tubes with 1 ml. of the 5 to 100 dilution, and 5 tubes with 1 ml. of the

5 to 1,000 dilution. After incubation at 37° C. for 48 hours, the number of gas-positive fermentations was noted and streaks from these tubes were made on eosin-methylene-blue agar plates. E.M.B. agar plates were used because they are believed to be slightly more selective than Endo's agar. After 24 hours, incubation colonies most resembling *E. coli* were picked and inoculated into lactose broth fermentation tubes. Those which failed to referment were classified as false presumptives, and discarded. From the positive tubes streaks were made upon Endo's medium to determine colony characteristics and insure the purity of the culture. Agar slants were made and saline suspensions from these used to inoculate tryptophane broth, Clark and Lubs medium, sodium citrate, and uric acid tubes. Readings were made

at 24 hours for indol production, and at 48 hours for the other tests except the methyl red reaction, which was determined after 96 hours' incubation. An organism was considered to be of fecal type if it was a Gram-negative rod producing typical *E. coli* colonies on Endo's medium, producing indol, and was methyl red positive, Voges-Proskauer, sodium citrate, and uric acid negative.

Twenty fillets purchased at intervals from May to August yielded 203 cultures producing gas in brilliant green lactose peptone bile broth in the primary inoculations. After repurification 181 of these refermented lactose, and of this number 60 were typical, according to the previous definition, of fecal *Escherichia coli.* Four of the 20 fillets did not show evidence of any typical fecal *Escherichia coli.* Five eviscerated haddock purchased during the same period yielded 44 gas positive tubes; 40 refermented lactose, and 4 were typical of fecal *E. coli.*

Brilliant green lactose peptone bile broth was used instead of the usual lactose broth because it was believed that this medium was more selective for organisms of the Gram-negative, lactose-fermenting type. From 6 fillets, where duplicate tubes were set up, lactose broth yielded 46 gas positives from which 10 typical *E. coli* were isolated, and brilliant green lactose peptone bile broth gave 54 positive gas tubes from which 17 typical *E. coli* were isolated.

False presumptive tests from the two sets of broths were about equal in frequency of occurrence. These apparent false presumptives may have been due to either the loss of the gas-producing organism on transfer, or to a non-colon type of symbiosis in the original direct inoculation.

Brilliant green lactose peptone bile broth alone was used for the remainder of the fillets. Table I shows the distribution of positive gas tubes from the dilutions of the fillet and fish.

The majority of isolations and the fewest false presumptive tests were obtained from the primary inoculation of 0.5 gm. flesh. The number of samples run is not large enough to consider this difference conclusive. Positive 5 to 1,000 tubes were obtained from 11 of 17 fillets and from only 2 fish.

Table II shows the distribution according to the 6 criteria mentioned of all the Gram-negative lactose-fermenting organisms isolated.

Of the cultures isolated from fillets, 60, or 30 per cent, were typical of fecal *E. coli.* From whole fish only 4 typical *E. coli* were isolated and the proportion of intermediates was higher. Gas pro-

duction was seldom observed in dilutions of 5 to 1,000 of whole fish flesh. This would indicate that if treatment and handling were in any way related to the number of positive gas tubes, and to the type of organisms found, then the whole fish were considerably better in sanitary quality than were the fillets.

DISCUSSION

These experiments have demonstrated the presence of bacteria of the coli-aerogenes group on the flesh of commercial fillets and whole fish; and *E. coli* characteristic of mammalian feces was present on many of the samples examined, particularly on the fillets. Since the work of Gibbons, Fellers, and others has shown that *E. coli* is not usually found in, or on, marine fish from deep water, it follows that the fish and fillets most likely become contaminated with these organisms during handling. The process of making fillets involves the more extensive handling and consequently results in greater possibility of contamination; this is shown by the greater abundance of *E. coli* found on fillets than on whole fish.

The presence of *E. coli* in oysters and clams is used as an evidence of pollution, and if such pollution is sufficiently serious the products are condemned. The data presented indicate that many fillets, and some whole fish, purchased at random from public markets are contaminated, but a different use should probably be made of the information. The fact that fish are well cooked before they are eaten minimizes, and in most cases removes, any danger of illness resulting from this type of contamination.

A test for *E. coli* is probably better qualitative evidence of careless handling than a total bacterial count, and a test for this, and perhaps related organisms, might be used for educational purposes, among those engaged in bringing fish to the consumer, in the effort to improve the methods of handling and marketing.

The significance of members, other than *E. coli*, of the coli-aerogenes group, is a controversial subject. The *Standard Methods of Water Analysis* of the American Public Health Association considers the presence of members of the group to be sufficient evidence of pollution to justify condemning water. However, prominent investigators, particularly Levine,[11] Tonney-Noble,[12] and Koser,[13] insist that only *E. coli* are from feces and that other members of the group are of little, or no, sanitary significance. The authors of this paper are inclined to accept the latter view.

The investigation here reported does not represent a sufficient number of samples to make the results conclusive. It is the intent, rather, to offer this preliminary study as a suggestion to laboratories concerned with the studies of fishery products that the occurrence of *E. coli* on fish and fillets is worthy of wider study. It is hoped that methods may be devised for evaluating the sanitary quality of these fishery products.

SUMMARY

1. Twenty commercial haddock fillets and 5 eviscerated haddock were purchased from local retail markets and examined for the presence of members of the coli-aerogenes group of bacteria.

2. Typical *Escherichia coli* were found on 16 of the fillets, and on 2 of the eviscerated fish.

3. Lactose-fermenting organisms other than *Escherichia coli* were commonly encountered on both fillets and eviscerated fish. Because of this fact, gas production from lactose broth tubes taken alone is not sufficient evidence of contamination. Differential tests should be made to determine whether or not the responsible organism is *Escherichia coli*.

4. Further investigation is recommended to study the possibility of using the occurrence of *Escherichia coli* as an index of the sanitary quality of marine fish and fillets.

Can the Health Officer Safely Utilize Prophylactic Immunization as the Sole Means to Control Canine Rabies?*

H. W. SCHOENING, V.M.D.

U. S. Bureau of Animal Industry, Washington, D. C.

THE answer to the question "Can the health officer safely utilize prophylactic immunization as the sole means to control canine rabies?" is definitely in the negative.

In controlling outbreaks of rabies it is essential that the cycle by which the disease is propagated from one susceptible animal to another be broken, so that the disease ceases when the last infected animal succumbs.

The successful use of a prophylactic vaccine as a sole means of controlling rabies would be predicated upon the assumption (1) that the vaccine is 100 per cent effective, and (2) that every dog is treated with such a vaccine.

So far as I am aware no biological product has yet been developed that is 100 per cent effective, rabies vaccines being no exception, and the ever-present stray dog precludes the possibility of treating the entire dog population.

Since it is apparent that the use of vaccines alone cannot be depended upon to control the disease, it seems desirable to discuss the part that vaccination may play in the control of outbreaks of rabies.

Such methods as licensing dogs in general, quarantine measures, and the impounding and disposal of stray dogs, have been used for years, and the success of these measures has been proportional to the vigor with which they have been prosecuted. In some countries, notably England, these methods have resulted in complete eradication of the disease.

Following the work of the Japanese investigators, Umeno and Doi,[1] the prophylactic, single injection method of vaccination of dogs was introduced into the United States as an added weapon in the control of rabies. That it has had extensive use is indicated by the records of the Division of Virus-Serum Control, of the U. S. Bureau of Animal Industry, which has jurisdiction over biological houses operating under federal veterinary license. From January, 1923, to January, 1934, approximately 3,700,000 doses of this type of vaccine were prepared by such commercial houses.

The use of prophylactic vaccination in conjunction with other measures in controlling rabies is predicated on the reduction of the susceptibility of dogs in that area to the disease, and the extent to which vaccination will be an aid depends on the efficacy of the vaccines and their proper administration. Since the proper administration of the vaccine is a technical procedure, this should be

---

* Read before the Laboratory Section of the American Public Health Association at the Sixty-fourth Annual Meeting in Milwaukee, Wis., October 10, 1935.

left in the hands of the veterinarian. To be of value, vaccination need not be 100 per cent, but it should be reasonably effective; it should be a safe procedure; and, lastly, the limitations of the method should be recognized.

The U. S. Bureau of Animal Industry has made experimental investigations of the efficacy of the prophylactic single injection canine rabies vaccines and at various times has published the results. In the first publication [2] 5 separate experiments were made, in some of which the results were favorable, and in others unfavorable. Those familiar with animal experimental work, particularly with rabies, are cognizant of the difficulties of this type of experimentation and of the varied results that may occur. In rabies work, the type of material used to expose animals, the method used, and variations in individual animals are factors which have a bearing on the results and at times are difficult to control.

It was found that while the fixed virus entering into the vaccine was attenuated, it was capable, under certain circumstances, of inducing the fixed virus disease, a feature quite objectionable in a prophylactic vaccine. Biological houses were required to change their methods of production so that the virus entering into the vaccine was killed. This is the type of vaccine that is now, and for some years has been, in use commercially in this country. The bureau's experimental work on this type of vaccine was reported in later papers.[3, 4] These experiments, while limited, indicated that resistance to rabies could be increased in many dogs by a single injection of vaccine. However, this resistance is only relative—in some animals it may be strong, in others weak, or lacking, so that some may be able to withstand actual exposure to the disease whereas others may not. The duration of immunity also probably varies. Experimental information indicates that appreciable immunity in some dogs may persist for at least a year. Immunity should not be expected to last longer.

Observations from the field use of the vaccine indicate that vaccination has been of value in the hands of many veterinarians. However, failures of the vaccines to protect have also been reported. These observations are in accord with our experimental work. The amount of exposure that an animal receives and the individual variations are no doubt factors that have a bearing on the effectiveness of vaccination.

It is important, therefore, to recognize that while the resistance to rabies of many vaccinated dogs may be raised, failures to protect can and do occur, and no false sense of security should prevail because of such vaccination.

Reports from the field indicate that many thousands of dogs have been vaccinated with no untoward effect from the vaccine itself. Occasional reports indicate that unfavorable reactions occur from the injection. These have been indicated by paralysis, for the most part transitory, although a few cases have had a fatal termination. No generally satisfactory explanation as to the cause of these adverse reactions has been advanced. The commercial vaccines in use in this country are killed by phenol or chloroform. Federal regulations require that the vaccines be injected subdurally into rabbits (the most rigid test available) as a test for viability of the virus before these are marketed. If the vaccines are properly prepared, they should contain no viable virus capable of producing the disease. When unfavorable reactions occur in dogs, it appears that these occur with certain lots of vaccine, and while we have examined such lots of vaccine, we have been unable to demonstrate the presence of living virus as a responsible factor. The idea has been put forth, however, that in some part of certain vaccines, viable virus may be present in larger portions

of brain tissue which may have escaped the action of the killing agent, and when injected into a particularly susceptible dog may result in a fixed virus infection. Other explanations have been suggested, viz., a rabies toxin, toxic material contained in the brain tissue entering into the vaccine, etc.

While field evidence on the use of vaccine indicates that untoward reactions occur infrequently, the fact that they can and do occur should be recognized. Much of the opposition by dog owners to vaccination is based on fear of these reactions. Dog owners are entitled to a frank appraisal of the vaccines. There is no doubt that vaccination has been unjustly accused of causing trouble in many cases in which it was in no way responsible.

Since vaccination may be a possible hazard to the dog, even though this may be quite remote, it would appear that the general use of vaccine should be restricted to actual or potential outbreaks of the disease.

Since there is a possibility of a negative phase following vaccination, it seems desirable to confine treated dogs for 2 to 3 weeks following vaccination.

It is desired to emphasize again that vaccination, no matter how effective, cannot in itself control rabies. The vigor with which such other control measures as licensing and quarantine, and the impounding and disposal of stray dogs are carried out will determine to a large extent the duration of outbreaks in communities.

Tuberculosis in Dairy Cattle

THE U. S. Department of Agriculture has reported an outbreak of tuberculosis in a herd of dairy cattle located at the Federal Experiment Station at Beltsville, Md. This herd which is used for experimental purposes has been accredited for tuberculosis freedom for 18 years and has been maintained almost entirely by replacements raised on the farm. In the last previous test in October, one reactor to tuberculin appeared. On January 16, 82 reactors and 11 suspect reactors were revealed.

In accordance with the policy of the Department of Agriculture, these affected animals are being slaughtered and subjected to post-mortem examinations. The sudden appearance of the disease and the rapid spread were very unusual and no explanation could be found for the extensive outbreak. A study is being made to determine whether a virulent strain of the bovine organism gained access to the herd or whether, possibly, sabotage was responsible.

The situation illustrates a condition which may face health departments which have depended upon examinations for freedom from tuberculosis in dairy herds carried out at intervals much longer than those indicated in this outbreak.

Encephalitis of the St. Louis Type in Illinois*

WINSTON H. TUCKER, M.D., PH.D.

Assistant Epidemiologist, Illinois Department of Public Health, Springfield, Ill.

THE occurrence of an outbreak of 1,097 cases of encephalitis in St. Louis during the summer and autumn of 1933 came as a surprise to the medical profession and public health officials in this country. A complete record of the St. Louis outbreak has been published by the U. S. Public Health Service.[1] The general apprehension felt at that time was particularly acute in Illinois because of the close proximity of the outbreak. Accordingly, the attention of the Illinois Department of Public Health became focused upon the St. Louis area for the purpose of controlling the possible spread of the disease in this state.

The character of the St. Louis outbreak reminded Illinois public health officials of a similar one in Paris, Edgar County, Ill., in August, 1932. At that time there were 38 cases which were diagnosed as epidemic encephalitis by the attending physicians and representatives of the Illinois Department of Public Health. An epidemiological report was published by Houston [2] in December, 1932. The source of the illness could not be determined. Food and water supplies appeared to have no relation to the outbreak. None of the patients had been away from home, and no deviation from routine living habits of these persons had taken place. In 2 instances, relatives who had nursed patients became ill with encephalitis 15 and 6 days respectively after exposure. As 14 of the 38 patients died, there was a fatality rate of 37 per cent. No bacteriological or pathological studies were conducted. A survey of the recovered patients in May, 1935, revealed no sequelae attributable to their illness in 1932.

In the studies of the St. Louis outbreak of 1933, several strains of filtrable virus were isolated from brains of fatal cases by Muckenfuss, Armstrong, and McCordock,[3] and by Webster and Fite [4] by intracerebral inoculation of laboratory animals. This virus will be referred to as the St. Louis virus. Webster and Fite [4] found that blood from several of the recovered St. Louis patients contained specific protective properties against this virus when injected into mice. Shortly after, Webster and Fite [5] reported that 5 specimens of blood from persons who recovered from encephalitis in Paris, Ill., in 1932, also contained specific protective properties against the St. Louis virus.

Wooley and Armstrong [6] reported that blood specimens from 10 of 12 persons who recovered from this disease in Paris in 1932 contained specific protective properties against the St. Louis virus. These studies proved that the outbreak at Paris was caused by the same infecting agent as that at St. Louis. Blood collected by the writer in February, 1935, from 10 of the recovered patients in the 1932

outbreak in Paris, were submitted to the National Institute of Health* and the Rockefeller Institute for Medical Research* for conducting additional protection tests. It was found that blood from 7 of the 10 still contained protective properties against the St. Louis virus 30 months after the epidemic. As a result of all protection tests on blood specimens from the Paris outbreak of 1932, it was found that 13 of the 21 recovered patients had developed specific protective porperties against the St. Louis virus.

* Results of the studies on blood specimens from Illinois were reported in personal communications to Dr. Frank J. Jirka, Director of the Illinois Department of Public Health. We wish to express the appreciation of the Illinois Department of Public Health to Drs. G. W. McCoy, J. P. Leake, and Charles Armstrong, of the National Institute of Health, and to Dr. Leslie T. Webster of the Rockefeller Institute for Medical Research for their coöperation in these studies.

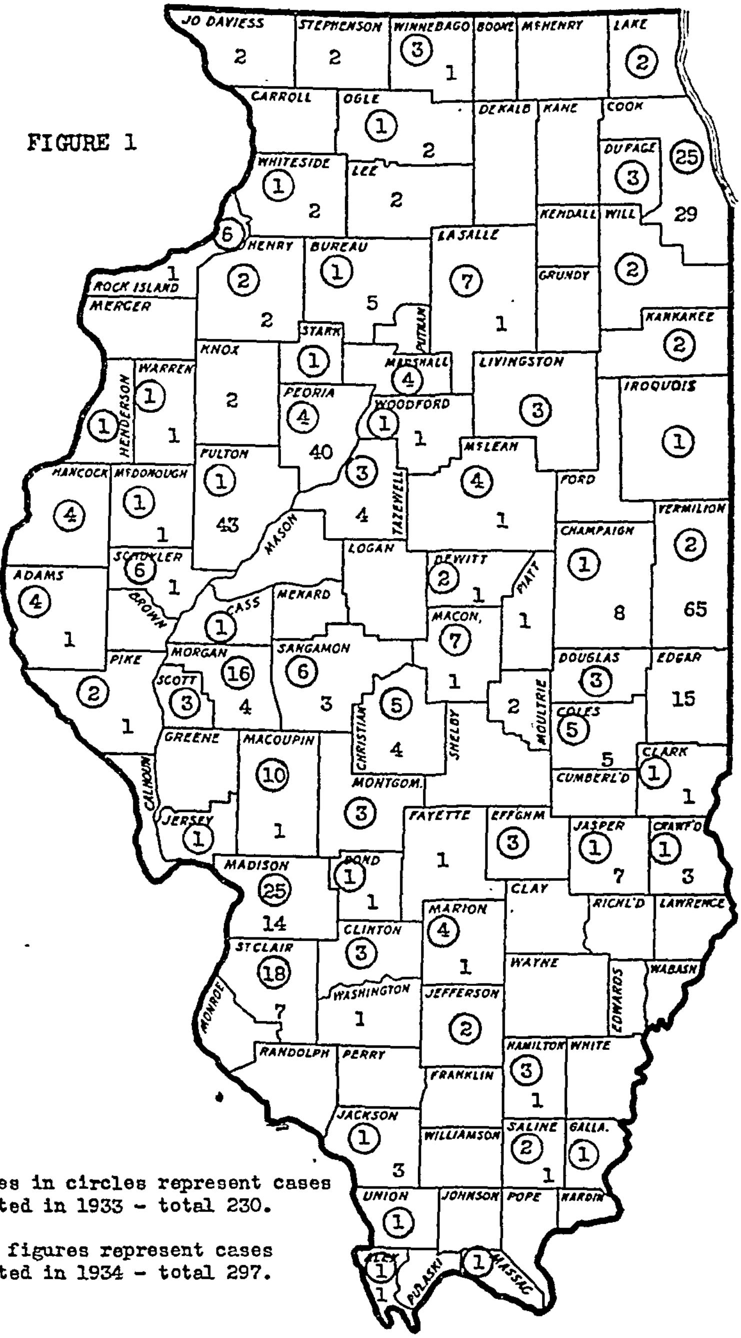
More cases of encephalitis occurred in Edgar County in 1932 than in any other county in the state (Table I). This small community had a morbidity rate of 152 per 100,000 population as compared to 100 in the outbreak in St. Louis in 1933. As in St. Louis, the largest number of fatalities occurred in persons in the upper age groups.

During the outbreak in St. Louis in 1933, 177 cases of the disease were recognized in Illinois, most of which occurred in Madison and St. Clair Counties, which are nearest St. Louis (Figure I).† No cases of this type of encephalitis occurred in Edgar County during 1933. The fatality rate, 35 per cent (Table II), was almost twice that of St. Louis,

† An analysis of the symptoms and physical findings in the outbreaks of 1933 and 1934 in Illinois has already been published.[7]

CASES OF ENCEPHALITIS (ALL TYPES) IN ILLINOIS
REPORTED BY COUNTIES 1933 AND 1934

FIGURE 1



Figures in circles represent cases reported in 1933 - total 230.

Plain figures represent cases reported in 1934 - total 297.

20 per cent, during the corresponding period. The writer collected no specimens for the detection of protective properties in the blood of patients who recovered from encephalitis in Illinois during 1933.

As in the summer of 1933, there was a severe drought in Illinois in the summer of 1934. Early in August, the number of cases of encephalitis increased very rapidly, the peak being reached on September 1, following which there was a gradual decline during September and October. In contrast to 1933, when most of the cases of encephalitis occurred in counties near St. Louis, the largest numbers of cases in 1934 (Figure I) occurred in counties remote from the St. Louis area. During August, September, and October, 1934 (Table III), 234 cases of encephalitis occurred throughout the state with a fatality rate of 22 per cent, about the same as that in the St. Louis outbreak during 1933. It is of interest to note that Chicago escaped this type of encephalitis during the past 3 years, when it was prevalent in other sections of the state.

Edgar County was one of those reporting a large number of cases during 1934. The illness was not confined to persons in the upper age groups as in 1932 (Table IV). Most of the patients were residents of Paris. Of the blood specimens taken in February, 1935, from 9 of the 13 recovered patients, 5 were shown to contain protective prop-

* Complete figures for 1935 are included for purposes of comparison.

erties. Of particular interest is the fact that 1 of these persons was the 15 year old son of one of the recovered patients from the 1932 outbreak. Blood from both father and son contained protective properties. Thus, it was found that blood from 18 of 26 recovered patients from the 1932 and 1934 outbreaks in Paris showed specific protective properties against the St. Louis virus.

Of specimens of blood taken in October, 1934, from 21 of the recovered patients in Vermilion County who had had encephalitis during the preceding 2 months, 13 were found to contain protective properties against the 1933 St. Louis virus. Similarly, of blood specimens from 6 patients in Fulton County, 3 were found to contain protective properties. However, specimens of blood from 19 recovered patients in Peoria County failed to show protective properties against the St. Louis virus. These findings are interesting, in view of the fact that the disease in Peoria County was the same clinically as in other sections of the state. One is led to speculate upon the possibility of an unrelated virus which causes a similar disease, particularly in view of the studies of Armstrong and Wooley [8] on a second virus isolated from the brain of a patient who died in St. Louis in 1933, which caused lymphocytic choriomeningitis in mice. These investigators [8] found that the blood of a patient in Vermilion County who recovered from encephalitis in 1934, showed strong protective properties against the virus of choriomeningitis, in addition to protective properties against the St. Louis virus (Freeman strain).

Table V shows the number of cases of encephalitis of all types* reported to the Illinois Department of Public Health during the past 11 years. The increase in the number of cases during August, September, and October during 1932, 1933, and 1934 is worthy of note. The increase during the early months of 1935 is due to cases of post-infectious encephalitis following chicken pox, measles, and mumps, and not to primary encephalitis. With the appearance of mild weather in June, post-infectious encephalitis decreased. During the

* In *Monograph Number 214*, the U. S. Public Health Service classifies encephalitis as follows:

1. Infectious encephalitis:
   1. Type A, or Economo or lethargic type, chiefly sporadic
   2. Type B, chiefly epidemic
      (a) Japanese form
      (b) St. Louis form
   3. Other types, possibly the Australian
2. Post or para-infectious encephalitis, chiefly seen following measles, smallpox, vaccinia, or chicken pox

summer and autumn months of 1935 there was no increase in Type B encephalitis comparable to that of the preceding 3 years. Most of the reported cases during the summer of 1935 were Type A, or the Economo type.

SUMMARY

1. Outbreaks of encephalitis of the St. Louis type occurred in Paris, Edgar County, Ill., during 1932 and 1934 with a fatality rate of 31 per cent. Of 26 blood specimens from recovered patients, 18, or 70 per cent, were found by investigators in the National Institute of Health and the Rockefeller Institute for Medical Research to contain protective properties against the St. Louis virus.

2. During the course of the outbreak of encephalitis in St. Louis in 1933, 177 cases were reported in Illinois, with a fatality rate of 35 per cent.

3. During the summer and autumn of 1934, 234 cases of primary encephalitis were reported in Illinois, with a fatality rate of 22 per cent. Vermilion, Fulton, and Peoria Counties reported the largest numbers of cases.

4. Of 21 blood specimens from recovered patients in Vermilion County in 1934, 13, or 64 per cent, contained protective properties against the St. Louis virus.

5. Of 6 blood specimens from recovered patients in Fulton County in 1934, 3, or 50 per cent, contained protective properties against the St. Louis virus.

6. Blood specimens taken from 19 recovered patients in Peoria County in 1934 failed to show protective properties against the St. Louis virus. In view of the similarity of the clinical symptoms of these persons with those suffering from primary encephalitis in other sections of the state, the possibility that the illness was caused by an entirely unrelated virus should be considered.

Too Many Claims Spoil the Medicine Man's Game

ALTHOUGH not nearly so common as they used to be, there are still occasional quack medicine vendors who stick to the old and illegal labels that claim for their nostrums curative powers over at least a good part of the ills and ailments that affect mankind.

Recently, for example, drug inspectors picked up samples of what were labeled "Devonshire's Earth Salts," marketed by F. S. Powers & Co., Crystal Lake, Ill. These were offered as a treatment for the following assortment of diseases and conditions: Pneumonia, cancer, diphtheria, typhoid fever, kidney and bowel trouble, appendicitis, intestinal worms and tape worms, locomotor ataxia, nervous disease, rheumatism, stomach trouble, skin diseases, malaria, high blood pressure, boils, abscesses, goiter, tumors, stomach ulcers, chills, colds, bronchitis, snake bites, delirium tremens, diabetes, venereal diseases, heart trouble, sterility in men and women, and also for "other disease conditions."

The nostrum got into interstate commerce and that brought it under the Federal Food and Drugs Act which penalizes sweeping claims not founded on fact and contrary to medical experience. A Federal court fined the seller.—U. S. Dept. of Agriculture *Release*, Feb. 16, 1936.

Dust Determinations*

E. C. BARNES

Medical Department, Westinghouse Electric and Manufacturing Company, East Pittsburgh, Pa.

RESEARCH and experience have shown that concentration, composition, and particle size distribution are the main factors to be considered in determining if any particular dust will cause pneumoconiosis. The length of exposure to a harmful dust is a very important factor in actually producing the pneumoconiosis.

CONCENTRATION

In the United States the standard method of determining the concentration of a dust for industrial hygiene work is by use of the Greenburg-Smith impinger sampling instrument and the standard microscopic technic as described by U. S. Public Health Service.[1]

Many variations of this standard technic, such as using higher magnification for counting, darkfield illumination,[2] different sampling liquids, etc., have been employed in making dust counts—all with the purpose of obtaining a more accurate measure of the dust concentration to explain the harmfulness or non-harmfulness of certain dusty conditions.

After making several studies of dust conditions in industrial plants, it was believed that there should be a much simpler, faster, and more accurate method of determining the number concentration of dusts; a method which would eliminate many of the undesirable features of impinger determinations. Some of the objections which have been brought against the impinger method are:

1. The time required for obtaining results is long.
2. The dust is entrained in a liquid medium, where some particles may be soluble, and particles may coagulate or stick to the container.
3. Particles less than 0.7 to 0.8 microns are not counted.
4. Particle size determinations are not readily obtainable.
5. All aggregates of particles which may exist in the air are broken up.
6. Solid particles are sometimes fractured when they strike the impinger plate.
7. The efficiency, although high, is not 100 per cent and apparently decreases with particle size.

A consideration of other methods of sampling and counting showed that they all had many disadvantages and limitations. Probably any method which can be devised will have at least some of these objectionable features.

The thermal precipitator as developed by Professor Whytlaw-Gray and Dr. Lomax, and further improved and described by Green and Watson,[3] appears to have overcome many disadvantages of other methods. In this sampler the dusty air is drawn through a narrow rectangular channel 0.051 x 1.0 cm. at 6.5 c.c. per minute. The dust is deposited thermally, from a hot wire across the center of this channel to two cover slips which are held along the sides of the channel. The dust is

* Read before the Industrial Hygiene Section of the American Public Health Association at the Sixty-fourth Annual Meeting in Milwaukee, Wis., October 8, 1935.

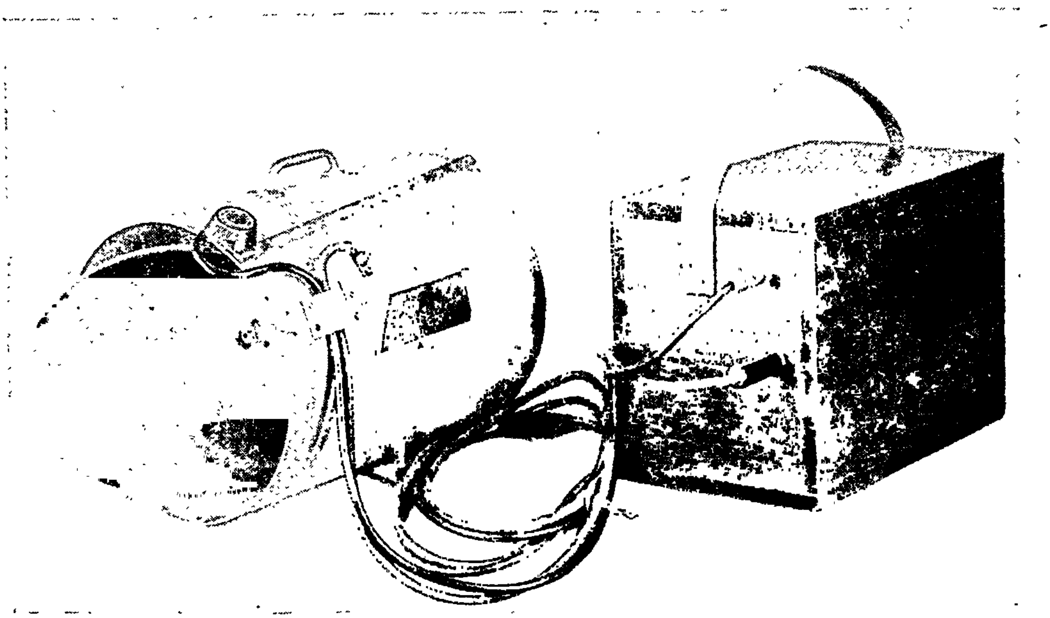

FIGURE I—Sampling Instrument and Power Supply

thus deposited in a narrow strip across two cover slips, giving a record similar to that of the Owens Jet Dust Counter. Its efficiency is claimed to be practically 100 per cent and the sample is obtained in a desirable condition.

Working in conjunction with Mr. Penney of our Research Department we have developed an Electrostatic Dust Count Sampler which I feel gives a desirable type of sample, the efficiency of the sampler being practically 100 per cent. A detailed description of this sampler will be given in the *Journal of Industrial Hygiene*, and only a brief description of it is given here.

A sample of the dusty air is trapped in a cylinder and deposited electrostatically over its inside surface. A microscope slide placed in one side of the cylinder receives its proportionate share of the total dust, the dust particles being, in general, uniformly distributed over the slide. This slide can then be removed, covered with a rectangular cover slip and examined microscopically.

The sampling instrument and its power supply are shown in Figure I. The sampling chamber consists of an aluminum cylinder 9″ in diameter and 12″ long, the ends of which are covered by disks of micarta. These ends, which support a fine ionizing wire axially through the center of the cylinder, can be opened and closed by the knob near the top of the cylinder. The slide holder as shown in Figure II holds a 25 x 75 mm. microscope slide under the two screws, the upper half being hinged to cover the slide. This holder fits into the opening in the side of the sampling chamber with the slide facing inward.

The sample is trapped by opening the ends, moving the cylinder to the exact sampling location, and closing the ends. Then the slide holder is opened and the dust deposited, this requiring about 15 seconds. A special microscope slide is used, as it must have a conducting surface over it to prevent distortion of the electrostatic field in the cylinder. These slides are prepared by a glass laboratory and are transparent and conducting, and the glaze is permanent. They cannot be used for darkfield illumination as obtained at present due to sub-microscopic particles in this

coating but they are entirely satisfactory for any lightfield determinations. This is not considered a serious disadvantage as many data indicate there are only a small percentage of particles less than 0.2 microns in industrial dusts. It is hoped that the slides can soon be obtained with a satisfactory surface for darkfield illumination so that the necessary research work on the finer particles can be carried out. Some research being carried on at present indicates that it may be possible to construct a sampler of this type which will use a regular microscope slide.

An advantage of this sampler is that an instantaneous sample can be taken when so desired. However, this is also a disadvantage since it cannot take a continuous sample. This objection is partially overcome since it takes a sample of about ½ cu. ft. at a time, and several samples can be taken on the same slide at intervals of about 15 seconds for short time variations; or several minutes for longer time variations.

These two samplers, the thermal and electrostatic, offer many advantages for sampling industrial dusts. It is sincerely hoped that after some experimental work one or the other can be adopted for general dust counting work.

COMPOSITION

The determination of the composition of a dust is of utmost importance since it has been shown that only certain dusts produce pathological changes in the lung tissues. Apparently the mineralogical composition of many dusts is the factor of most importance.

The mineralogical composition of the larger dust particles or of pieces of the original mineral can in general be made with the petrographic microscope, but for most dusts the greater percentage of the particles is below this limit and cannot be determined in this way. There are a very few minerals which

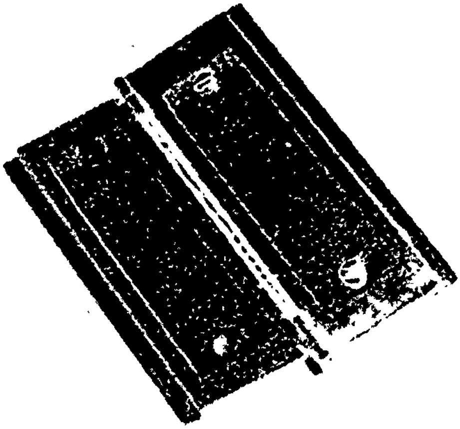

FIGURE II—Slide Holder

can be identified in the smaller particle sizes by a consideration of shape and certain optical properties.

The chemical composition of the dust can be accurately determined, and often a close approximation to the percentage of mineral constituents can be estimated from a complete chemical analysis of the sample and consideration of the chemical composition of the original materials.

For chemical analysis, the actual air-borne dust should be used, but it has been difficult to obtain a sample sufficient in quantity, but recent research has made it possible to build a small electrostatic air cleaner which can be used for this purpose. This will remove practically all of the dust from air which is drawn through by a small fan at the rate of 125 cu. ft. per minute. Its efficiency against fine particle smokes is 99.5 per cent by weight.

The cleaner consists of an ionizing chamber at the top and a group of parallel plates where the dust is deposited. The dust can then be brushed from the plates and used for chemical or other analyses. I will not give a theoretical discussion of the operation of this cleaner as it has not yet been published by our Research Department.

The complete sampler is shown in Figure III. It is 26″ high and 10″ x 16″ at the base, its weight about 50 lb. The air is drawn in at the top and downward through the sampling chamber by a small fan at the bottom of the cabinet. The ozone generated by the sampler is less than 1 part in 10 million. The power supply, which is located in the compartment at the rear, consists of a transformer, 2 rectifier tubes, and a condenser. It supplies 12,000 volt DC to the ionizing chamber and 4,500 volt to the plate assembly. The entire sampler is operated from any 110 volt, 60 cycle supply.

With this sampler it is possible to obtain a gram or more of dust in several hours in most dusty places. This sample can be used for accurate chemical analysis and for many other desirable determinations.

PARTICLE SIZE

Due to the research work of Gardner and associates [4] of Saranac Lake, it has been shown that in general the smaller sized particles are more active in producing fibrotic changes in the tissues where the dust lodges. This indicates that a very fine dust would be more harmful than a similar dust of large particle size.

Independent investigators have found that the particle size distribution of most industrially generated dusts is approximately the same. However, different investigators give widely different values for this. In general, this average particle size is from 0.6 to 1.5 microns.[3, 5, 6, 7]

No doubt some of these differences are due to different sampling methods and different microscopic technic; however, the microscopic magnification has been similar in most cases, and the minimum visible particle sizes should be similar.

The Owens Jet Dust Counter was used as the sampling instrument in most cases, and although its efficiency is questionable, the results should be comparable.

These indicate that the average particle size of different industrial dusts is quite different, and further show that a standardization on the best method would increase the value of the results many times.

The measurement of particle size by use of the filar micrometer is tedious and difficult for the smaller particles. The method of using a comparator graticule [6] in the eyepiece of the microscope is much easier. However, a method of micro-projection has been developed by Brown and Yant at the Bureau of Mines and is described in detail by them.[8] This is apparently the simplest, quickest, and most accurate of the various methods.

FIGURE III—The Complete Sampler

SUMMARY

A brief discussion of the standard dust counting method is given and several of the disadvantages enumerated. A consideration of the thermal precipitator and an electrostatic dust count sampler shows that at least some of the disadvantages have been overcome in these samplers, and this suggests that they are probably more desirable methods for dust counting. In determining the composition of an airborne dust it has been difficult to obtain a sample sufficient in quantity for chemical analysis, but a sampler has been developed for this purpose and it is described.

Particle size distribution of a dust is important, and data are given to show that the particle size distribution of dusts as determined by different investigators show marked variations. The best method of sampling and determination should be adopted as a standard. The method of microprojection seems to be the simplest, quickest, and most accurate.

DISCUSSION

J. J. BLOOMFIELD

Sanitary Engineer, U. S. Public Health Service, Washington, D. C.

In presenting his electrostatic dust sampling instrument and recommending its use, Mr. Barnes has premised its advantages on presumed faults of the impinger apparatus. The criteria which should be used in the selection of a dust sampling instrument for industrial hygiene studies are the collecting efficiency of the device, its ability to obtain large samples in a relatively brief period of time, its portability, its small errors in analysis, and, finally, the ease with which a sample once obtained may be analyzed. Mr. Barnes has listed 7 objections which have been brought against the impinger apparatus and the present method of analysis of impinger samples as conducted by the Public Health Service. Let us examine these objections in the light of the above criteria, and apply these same criteria to the instrument and method of analysis developed by Mr. Barnes, and described by him in the present paper.

The instrument described by Mr. Barnes is capable of taking an instantaneous sample of ½ cu. ft. volume. Mr. Barnes realizes the disadvantages of not being able to collect a continuous sample, and states that this objection is partially overcome by taking several samples on the same slide. Such a practice is apt to lead to erroneous results, due to the fact that the subsequent dust particles may be

deposited on those already collected on the slide, thereby yielding lower results. Such has been the experience with certain types of impingement devices in which the dust is deposited on a glass slide. If several slides are used, then the method becomes complicated.

Mr. Barnes's second objection is that the dust is entrained in a liquid medium where some particles may be soluble and others may coagulate. The Public Health Service recommends that samples obtained with the impinger be analyzed as soon as possible, usually within 24 hours of collection. It is felt that most mineral dusts of hygienic significance are not sufficiently soluble in such time to result in a significant loss of the sample. In our 12 years' experience with this instrument, we have had very little trouble with coagulation or flocculation.

The third objection is that it is not possible to count dust particles less than 0.7 to 0.8 μ in size. It is true that the microscopic technic used by us fails, in dealing with highly refractile dusts, to reveal particles less than 0.7 μ, but our work has shown that the number of such particles present in industrial atmospheres is comparatively small. Particle size studies conducted by us have shown that about 25 per cent of the suspended dust in the air is less than 0.7 μ. Moreover, it has as yet not been definitely established that these small size particles are of more pathological significance than those say from 0.7 to 3 μ. For these reasons, it is felt that our present technic reveals the significant size dust particles in the air of industrial establishments.

The fourth objection is that particle size determinations are not readily obtainable from impinger samples. Although in all such studies by us we have resorted to the Owens jet dust counter for particle size measurements, we have also had very little difficulty in preparing specimens for such measurements from dust collected by the impinger. This technic is described in *Public Health Bulletin No. 217.*

The statement that aggregates of particles which may exist in the air are broken and that solid particles are sometimes fractured when they strike the impinger plate, is not supported by proof.

The last objection, that the efficiency although high is not 100 per cent, cannot be considered seriously in view of the fact that independent research workers have shown that the impinger apparatus collects industrial dusts with an efficiency of 98 per cent plus.

It is apparent, therefore, that when judged in the light of the criteria suggested, the impinger apparatus is shown to be an excellent instrument for the purpose intended, namely, the evaluation of the dust hazard. Many years of use of this instrument, not only by us but by workers elsewhere, have shown it to be a device which can be employed for sampling in both high and low dust concentrations, with high efficiency, and the method of enumeration employed at present has been shown to be practical in that excellent correlations are obtained between the impinger dust results and clinico-radiographic studies of workers exposed to the dusts under consideration.

The electrostatic air cleaner described by Mr. Barnes, and which he developed for the purpose of obtaining large quantities of atmospheric dust for chemical analysis, will no doubt prove to be of value in certain types of investigations. However, as Mr. Barnes himself points out, in pneumoconioses studies it is more important to know the mineralogical composition of the dust than its chemical composition. In view of this, samples obtained with his device will be of little value, since it is well known that the small particles in the atmosphere are not capable of identification by petrographic technic. For this

reason, we have resorted to the collection of dusts settled at the breathing level, which contain not only the smaller size particles but also the larger ones, which settle out rapidly due to their size. Another objection to the air cleaner is that it also requires electric current. This is not available in many work places, such as in mines, quarries, etc.

Mr. Barnes's discussion on particle size presents an opportunity to express the speaker's opinion that the determination of particle size as a routine procedure in dust studies has been overemphasized. The reason for the average particle size being of variable value is not primarily due to the fact of personal error as Mr. Barnes says, but chiefly to the fact that even with the same dust, different sizes are produced by varying processes. For example, in working granite, a hand pneumatic tool will produce one average size, whereas the use of a machine pneumatic tool or a hand chisel will produce another average size. In other words, these variations are due to such factors, rather than different sampling methods or different microscopic technics. On the whole our measurements of thousands of particles of different dusts produced by various industrial processes have shown that although there is some variation, most of the dust particles (60 per cent) are between 1 and 3 μ in size. We have not found the filar micrometer method for such studies to be either tedious or difficult, and comparisons with photographic technics have shown it to yield comparable results. It is our feeling that all dusts present in industrial atmospheres are of a size small enough to gain access to the lung tissue, and that the important factors in the dust problem are the concentration and composition of the dust, and the years of exposure.

Should it be found that the dust determination method used by the Public Health Service is not revealing the significant sizes of dust, we would be the first to welcome any new device which might prove to be more efficient and better adapted for such studies. It must be borne in mind, however, that the instrument should be simple in construction and operation, and that the method of evaluation should be one which has small errors and is easily conducted. Mr. Barnes's electrostatic precipitator may have a slightly higher sampling efficiency than the impinger, but he has still to work out a method of enumeration which can be considered more practical than the present technic. In the final analysis, the method of dust sampling and counting which yields a practical index of the dustiness of an atmosphere is the one to employ. The instrument and method used by us over a period of many years has proved that high correlations may be obtained between dust counts in various industries and the degree of silicosis and tuberculosis among the workers exposed to the dusts investigated.

Fetal and Neonatal Mortality with Recommendations for Reduction*

F. L. ADAIR, M.D., F.A.P.H.A., AND EDITH L. POTTER, M.D.

Chairman of the Department of Obstetrics and Gynecology; and Douglas Smith Fellow and Instructor, Department of Obstetrics and Gynecology, University of Chicago, Chicago, Ill.

THE time from birth to 2 weeks is a unique epoch in the life of the individual. It is known as the neonatal period and during these days complete adjustment must be made from a sheltered intrauterine existence to one subject to the rigors of the external world. The causes of death in this period are largely distinct from those occurring later in life, but are closely allied with those operating as a cause of death before and during birth. For a complete understanding of the factors causing infantile deaths, study of antepartum and intrapartum deaths must be included.

At the Chicago Lying-in Hospital in Chicago there were 267 autopsies performed after deaths occurring in the first 10,000 consecutive deliveries, constituting 60 per cent of the deaths, and 61 per cent of the stillbirths. There were a total of 243 stillbirths after the 5th month of gestation and 198 deaths in the neonatal period, 75 per cent of which occurred inside of 24 hours, making a rate of 2.49 stillbirths per 100 live births and 23.9 neonatal deaths per 1,000 live births.

The most important causes of stillbirths are: asphyxia (38 per cent), due in large measure to placental and cord abnormalities and evidenced at autopsy by numerous petechial hemorrhages on the serous surfaces of the heart, lungs, thymus, liver, kidneys, or adrenals, together with marked engorgement of all peripheral vessels especially in the brain; intracranial hemorrhage (15 per cent), due almost invariably to birth trauma and demonstrated at autopsy by the presence of varying amounts of free blood in the intracranial cavity, either with or without falx or tentorial lacerations; major malformations (10 per cent). In only 1 case in this series could syphilis be proved the cause of death. In 22 per cent the fetus was macerated, indicating death some length of time before delivery but due to causes not determined. In 15 per cent there were no demonstrable abnormalities of any kind.

In neonatal deaths the most important factor is premature delivery of the fetus. In 32 per cent this was found as the only cause for failure to survive. Intracranial hemorrhage caused 27 per cent of the deaths, major malformations 12 per cent, asphyxia in which respiration was never established 4 per cent. In 10 per cent atelectasis of the lungs was the only

* Read before the Child Hygiene Section of the American Public Health Association at the Sixty-fourth Annual Meeting in Milwaukee, Wis., October 8, 1935.

pathologic lesion demonstrable and was listed as a cause of death. Although death is actually due to an insufficient gaseous exchange through the lungs the underlying cause is either depression of the respiratory center, lack of sufficient vitality to institute vigorous respiration or, more infrequently, inability to eject inspired amniotic fluid from the alveoli. Syphilis was proved in only 1 case, or less than 1 per cent.

By investigating the causes of death and by examining the summary in which they are listed according to the periods in which they operate, it may be seen that any effort to reduce neonatal mortality cannot be separated from the attempt to lessen the number of deaths in the ante- and intra-partum periods. The earlier in pregnancy death occurs, the less is known regarding the etiology and consequently the more difficult the problem of prevention. Abnormal development or faulty implantation of the ovum, abnormalities of the uterine mucosa, disturbance of ovarian or other endocrine function are the conditions usually surmised, but difficult to prove except in rare instances.

Later in pregnancy placental abnormalities are an important cause of death but impossible to prevent except in so far as in rare instances the child can be delivered by operative procedures when distress becomes apparent. Deaths from major malformations are inevitable and will always occur. They are due in large measure to abnormal germ cells and although various intrauterine conditions have been postulated as contributing factors none have been proved.

Of the known causes of death in the antepartum period those in which there is most hope of effecting a reduction are syphilis and the diseases specifically associated with pregnancy. Syphilis is a much more common cause of death in some areas than in others but it is the one condition which might be eradicated completely. Every woman should have a Wassermann test early in pregnancy. If it is positive or if there is any history of insufficiently treated syphilis, antiluetic treatment should be instituted at once. It is almost impossible to cure congenital syphilis after birth, but if treatment of the mother is started early in pregnancy the infant usually is free of the disease. Deaths from the various toxemias of pregnancy, including eclampsia, can be decreased by carefully watching the patient for impending development and instituting treatment promptly if symptoms occur.

In our present state of knowledge the entire attempt to lower antenatal mortality must be directed, with the exception of treating syphilis, toward general care and observation of the mother. She should be assured a diet adequate in calories, vitamins, and minerals, given adequate rest, and protected against emotional or physical fatigue. Any known endocrine abnormality should be corrected if possible. Medical examination should be sufficiently frequent to let no untoward symptoms go unnoticed. Examination should invariably include urinalysis and blood pressure estimation, together with the study of the general state of health.

In the intrapartum period by far the most common cause of death is trauma sustained during passage through the birth canal. Prenatal care should include taking accurate pelvic measurements and late in pregnancy determination of position of the fetus. If the measurements are adequate and the presentation cephalic with the occiput anterior, a normal delivery with a minimum amount of trauma may be anticipated. If the pelvic diameters are less than normal or the position any other than that stated, more trauma is apt to occur, the degree depending on

various factors concerned. In an anterior occipital presentation the plane of the head having the least circumference advances through the birth canal. In any other position a plane having a greater circumference must pass through and more molding must occur. When adequacy of the pelvis is questionable on manual examination, Roentgen measurements should be made. If the diameters are borderline, a test of labor may be given but if no progress is made a cesarean section must be done if the child is to be saved. When the measurements are definitely below normal, the infant should be removed by cesarean section before the onset of labor. If, when the patient goes into labor, the obstetrician is uncertain of the relation between the size of the fetal head and the maternal pelvis, he is under a great handicap in outlining his course if labor does not progress normally. If the fetus is battered against structures which it cannot pass untold harm is done both to it and to the mother.

In the interior of the head running longitudinally from the frontal region to the occiput is a downward midline extension of the dura known as the falx cerebri. In its posterior portion it is continuous with the tentorium cerebelli which lies at right angles to it and covers the cerebellum. Special reinforcing fibers are present near the free margin of the falx which divide at its posterior end and extend bilaterally along the free margins of the tentorium. Increase in any diameter of the head, especially if asymmetrical, causes tension on these free margins; if the tension is sufficient the fibers may part. Rupture occurs most commonly in the tentorium near the attachment of the falx and may be unilateral or bilateral. At the same time tears permitting extravasion of blood into the cranial cavity are usually produced in the sinuses coursing through these structures. Increase in antero-posterior diameter may cause rupture and hemorrhage from the great vein of Galen which is stretched between the straight sinus in the tentorium and the circle of Willis, even in the absence of sufficient strain to cause lacerations of the falx or tentorium.

Undue stretching of the structures within the cranial cavity is the usual cause of intracranial hemorrhage and is by far the most common type of birth trauma. By referring to the summary of causes of death, we find that it occurs in many conditions—with sudden change of forces on the head, as in precipitate deliveries, in very long labors where there is excessive head molding, and in breech presentations where there is often more compression of the head than it can tolerate. The most common cause is the application of forceps to the head and in this field improvement of obstetric technic holds forth the greatest hope for diminution of injuries. Forceps should not be applied without definite indications and then only by a skilled operator.

Other less frequent injuries causing death are fracture of the cranial bones, a separation of alar and basilar parts of the occipital bone with injury to brain substance by intrusion of the lower free margin of the alar portion, fracture of vertebrae, and rupture of internal organs with ensuing hemorrhage.

Although birth injuries can never be completely eliminated as a cause of death, improvement in obstetric judgment and technic may cause a marked reduction.

In the postpartum period the most common single cause of death is prematurity. Anything which will prolong the period of gestation to normal will increase the infant's chances of survival. Here again the most important factor is adequate prenatal care, although with the best of care and the most constant supervision, labor oc-

casionally sets in prematurely without a demonstrable cause. If it is deemed advisable to terminate labor, a viable infant cannot be obtained before the end of the 28th week, and even then it is very apt to perish. If an elective cesarean section is to be performed it should be done as near term as possible.

When an infant is born prematurely it must be very carefully protected. Maintenance of temperature must be begun from the moment of birth, and to conserve its energy feeding is best carried on by gavage. Mother's milk is the only satisfactory diet and should be obtained if at all possible. All external sources of infection must be eliminated. With skill and patience it is often possible to raise surprisingly small premature infants.

Death from birth trauma occurs usually in the first few hours after birth, and is similar in its etiology and manifestations to that occurring during delivery. If an infant is born alive but shows evidence of birth trauma it is treated the same as a premature infant in an attempt to prevent increased hemorrhage.

In the postpartum period, that time immediately following delivery is the most important. To give any infant the best chance for survival the normal temperature should be maintained from the moment of birth in order to prevent an initial chilling. The respiratory passages are freed of mucus and for this purpose a soft rubber catheter may be of great value. If respiration is delayed, administration of an oxygen (95 per cent) carbon-dioxide (5 per cent) mixture, together with artificial respiration should be used if available; otherwise, resort may be had to mouth to mouth breathing. Measures formerly in vogue, such as swinging the infant by the feet, tubbing alternately in hot and cold water, are more deleterious than helpful. Reasons for delayed respiration may be depression of the respiratory center due to interference with blood supply before or during birth, intracranial hemorrhage, aspiration of amniotic fluid, narcosis of the mother, etc.

Adequate care of the infant after it leaves the birth room consists in maintaining its normal body temperature, keeping it free from contaminating influences, and insuring it sufficient assimilable food. Breast milk is the most desirable diet but if this cannot be obtained in sufficient quantities, carefully chosen complementary food is added. The mouth and skin of the infant are very susceptible to infection. Swabbing out the mouth is apt to injure the delicate tissues and usually it remains in better condition if left entirely alone. The hands of the nurse are washed before the handling of each infant to prevent any possible skin contamination from one to another. Prevention of pneumonia, contagious diseases, etc., during the neonatal period is largely the same as with older individuals and consists chiefly in keeping the infant free from any possible source of infection.

SUMMARY OF CAUSES OF FETAL AND NEONATAL DEATHS

ANTENATAL PERIOD

Placental:

1. Abruptio placenta
2. Placenta previa
3. Massive infarction
4. Insufficient size

Cord:

1. Compression
2. Obstruction due to knots, thrombi, etc.

Maternal:

1. Toxemias, including eclampsia
2. Chronic degenerative diseases, such as cardiac decompensation, glomerulo-nephritis, etc.
3. Infectious diseases, including syphilis
4. Unknown causes which may be vitamin or mineral deficiencies or endocrine imbalance
5. Physical injury

TABLE I

PRIMARY CAUSE OF DEATH AND STILLBIRTH IN 267 NECROPSIES OCCURRING IN 10,000 CONSECUTIVE DELIVERIES

Cause of Death	*Premature*	*Term*	*Stillborn*	*Total*
Previability (no abnormalities)	15	..	..	15
Prematurity (no abnormalities)	25	..	..	25
Major Malformations	7	8	15	30
Asphyxia Total	1	4	55	60
Cause Undetermined	..	4	15	..
Toxemia and Eclampsia	..	..	8	..
Abruptio Placenta	..	..	20	..
Placenta Previa	..	..	6	..
Cord Obstruction	..	..	6	..
Plug in Bronchus	1	..	..	..
Atelectasis—Cause Undetermined	1	10	..	11
Hemorrhage				
Intracranial	13	19	21	53
Visceral	1	..	1	2
Maceration—Cause Undetermined	..	..	33	33
Miscellaneous				
Peritonitis	1	1	..	2
Syphilis	1	..	1	2
Congenital Fetal Hydrops	1	1	..	2
Pneumonia	..	3	..	3
Emphysema	..	2	..	2
Endocarditis (?)	..	1	..	1
No Abnormality	..	7	19	26
	66	56	145	267

Fetal:

1. Developmental abnormalities
2. Diseases specific to the fetus, as erythroblastosis with edema, osteogenesis imperfecta, etc.

Operative termination of labor:

1. Application of forceps with too great or unequal pressure on the head
2. Version and extraction, for same reasons as in spontaneous breech deliveries.

INTRANATAL PERIOD

All conditions which produce fetal death in the antenatal period may also cause death during labor. In addition, there is the very important factor of birth trauma. Among the conditions under which it may occur are:

Spontaneous termination of labor:

1. Precipitate delivery
2. Prolonged labor due to such causes as an abnormal pelvis, disproportion between fetal head and maternal pelvis, posterior position of the head, premature rupture of membranes, etc.
3. Breech presentations in which there is too rapid head molding or too great pressure against the symphysis pubis
4. Difficult extraction of the shoulders with excessive traction or rotation of the neck
5. Rough handling of visceral portions of fetus during delivery

NEONATAL PERIOD

Inability to become adjusted to an independent existence due to:

1. Any factor operating in the antenatal and intranatal periods, either alone or in combination with those below
2. Prematurity
3. Inherent constitutional weakness
4. Abnormalities, such as cardiac defects, gastrointestinal atresia, renal aplasia, etc., which were not incompatible with intrauterine life.

Conditions not intrinsically related to the establishment of an extra-uterine existence:

1. Acute infections of skin, mucous membranes, respiratory system, gastrointestinal tract, blood stream, etc.
2. Inanition due to improper or insufficient feeding
3. Insolation and refrigeration
4. Diseases peculiar to the neonatal period,

as hemorrhagic diathesis, icterus gravis, etc.
5. Miscellaneous diseases occurring in children and adults but rarely affecting the newly-born infant.

CONCLUSIONS

Although in the last 20 years there has been a marked decrease in the death rate under 1 year, there has been a smaller decrease in the death rate for the first 2 weeks of life. There has been practically no change in the rate for stillbirths since vital statistics on this subject have been collected.

Causes of death are best divided into those operating in the antepartum, intrapartum, and postpartum periods. In the antepartum period placental abnormalities, cord compression, developmental abnormalities of the fetus, and diseases of the mother incident to pregnancy are the most common causes; in the intrapartum period trauma with resulting intracranial hemorrhage is responsible for the majority; in the postpartum or neonatal period prematurity and birth trauma are the most common causes of death.

Attempts to lower the neonatal death rate cannot be made without also attempting to lower the stillbirth rate, for deaths in both groups are frequently due to the same fundamental causes.

The main points to be stressed in attempting to prevent antenatal, intranatal, and neonatal deaths are: better prenatal hygiene, immediate and appropriate treatment of toxemias, correction of malpresentations, appropriate treatment of cases of contracted pelvis, prevention of the onset of labor until as near term as possible, more skilled obstetric technic, and better immediate care of the new-born child, especially those born prematurely.

EDITORIAL SECTION

Expressions of opinion and statements of supposed facts are published on authority of the writer under whose name they appear, and are not to be regarded as expressing the views of the American Public Health Association, unless such statements or opinions have been adopted by vote of the Association.

THE PROBLEM OF THE VOLUNTARY HEALTH AGENCIES

RECENT statistics published in this *Journal* under the auspices of the Committee on Administrative Practice have made it clear that during the depression years, funds available for voluntary health agencies have decreased much faster than appropriations for official agencies. This must be a cause of grave concern since the voluntary health agencies, particularly the visiting nurse associations and preventive clinics, form an essential part of the public health program as a whole.

The health officer of a given community is the one person officially responsible to the people for the maintenance of its health services of all sorts. He should lead and direct the entire program, official and voluntary. If he is wise, however, he will in any given case utilize the particular agency which can carry on a given service most efficiently and most economically. In many instances, for example, the delegation of certain phases of public health nursing to visiting nurse associations which can carry such services on a generalized basis, has proved of great public benefit. Where this is the case it is entirely fitting and proper that such agencies should be aided by grants from the city treasury, made through and under the supervision of the health officer. If, however, the community through its voluntary funds does not make proper provision for its nonofficial health agencies, the health of the community will inevitably suffer.

It seems evident that in many communities throughout the country a more or less organized effort is being made to reduce the proportionate grants from Community Chest funds to the health agencies. This is in part a reflection of a general social viewpoint which favors the widest possible extension of government control in all fields. It is in part at least actuated by a desire to conserve Community Chest funds for the so-called " character building " agencies by shifting the health burden to the public purse. Although it is recognized that in many quarters the character building agencies may have been inadequately sup-

ported, we believe this tendency to reduce health agency support to be unwise and unfortunate. It may well be maintained that the care given to infants and young children by the public health nurses and the child health conferences definitely affects character building, just as do those institutions which provide leisure time activities in later life. All of us who are interested in the public health field should strive to see that the health agencies are not forgotten in the Community Chest program of the future.

TYPES OF THE DIPHTHERIA BACILLUS

IN 1931,[1] Anderson, Happold, McLeod, and Thomson devised a chocolate agar tellurite medium for the growth of the diphtheria bacillus, and by its use were able to divide the Klebs-Loeffler bacillus into three types—*gravis, mitis,* and "intermediate." They based their nomenclature on the relative severity of cases from which these types were isolated. Since that time a great deal of work has been done in England, which has in the main confirmed their findings, especially as regards the cultural characteristics of the three types of organism isolated. However, the findings concerning the type of cases from which these three varieties are isolated have been decidedly different.

The matter has been of sufficient importance to attract official attention, and in our review of the *Annual Report* of the Chief Medical Officer of the Ministry of Health for 1934,* we commented on some of the results. This report took up work done in London, Staffordshire, Edinburgh, Glasgow, Manchester, Hull, and other places. In certain articles it is stated that the clinical type due to the "intermediate" form is "only a little less severe" than that produced by *gravis.* Mild cases are observed from which either *gravis* or *mitis* are isolated and are clinically indistinguishable. In Hull and Leeds the *gravis* strain predominated. In Glasgow it was rare and *mitis* was common, while in Manchester the "intermediate" strains were most commonly found at the beginning of the study, but gave way later to *gravis* and *mitis.* In Staffordshire there was difficulty in classification, owing to the prevalence of atypical strains. In Edinburgh atypical strains were found, but were replaced later by "intermediates."

The correlation of the bacteriological findings with the clinical characteristics has, in the main, confirmed the original findings, though there have been many marked differences. In Manchester and Leeds the "intermediate" strains give a disease less severe than that produced by *gravis,* while in Hull, the "intermediate" strain shows a severity definitely between *gravis* and *mitis.* In London there was no evidence that the severest types of the disease were associated mainly with *gravis,* though later in the investigation an increase in the severity of the disease was noticed, and an increase in the prevalence of *gravis* strains was found.

The latest study[2] that has come to our notice is from Leeds, the city from which the original work emanated. Here again, the bacteriological findings agreed with those reported by the original investigators. There were no aberrant strains found and the "intermediate" types were 100 per cent typical. The report embraces 166 virulent strains isolated from typical cases of diphtheria occurring in Dundee and the surrounding district. The author, Dr. Murray, had 71 of these cases under his personal care. All the cultures fell clearly into one

---

* *A.J.P.H.,* Jan., 1936, p. 76.

of the three classes; 66 *mitis*, 10 *gravis*, and 90 "intermediate." Of the *gravis* strain, 9 out of the 10 were isolated from mild cases, while the greatest majority of the severe cases were due to the "intermediate," the case mortality for this strain being 11.1 per cent against 3 for *mitis*, and 0 for *gravis*.

There can be little question that the work of Anderson, Happold, McLeod, and Thomson has a real public health significance in addition to its scientific interest. The difference in findings referred to points clearly to the need for further investigations in a number of different places in England as well as in other countries. Ever since diphtheria has been known we have recognized that some epidemics are more severe than others. In recent years several epidemics of extreme severity have been reported without any clear reason for the unusual virulence shown.

Ever since the discovery of diphtheria antitoxin by von Behring, in Germany, and Roux, in France, we have reposed serene in the belief that antitoxin was the sovereign remedy, and nothing said here is intended to question the fundamental soundness of this belief. Indeed it is strengthened by the work discussed, at least as far as experiments on animals go, since the antitoxin in general use has been found to neutralize the toxin of *mitis*, *gravis*, and "intermediate" types. In human beings, cases from which the *gravis* is isolated do not respond favorably to the use of antitoxin, while those due to *mitis* and "intermediate" are favorably influenced.

NOTE: The authors of the original paper stressed only the *mitis* and *gravis* forms which they spoke of as the "two principal forms of the diphtheria bacillus." They, however, recognized the "intermediate" form in from 5 to 10 per cent of their cases. It is of especial interest to note that the organism known as Park No. 8, which is so widely used in this country and others for the production of diphtheria antitoxin, and is famous for its consistent production of a toxin of high potency, falls into this group.

PUBLIC HEALTH EDUCATION*

"Village of the Living Dead"—"Hundred of Miners' Lives Reported Lost from Silicosis, Occupational Disease; Congress Stirred; Employers Deny Unfairness."

Thus the *Literary Digest*, 354 4th Ave., New York, N. Y. (Jan. 25, 1936), presents to its readers the story of disease and death at Gauley Bridge, W. Va.

New York World-Telegram had pictures and a striking Rollin Kirby cartoon. Probably newspapers over the country carried news of the House committee hearing in Washington. And thus a public health situation was in the news.

Did any public health workers get any tie-up for a local dust and disease problem?

When Publicity Back-fired—In all probability Columbia University overplayed the announcement of the dental desensitizer which was in all the newspapers about a month ago. Dentists' patients have been led to expect far more than there is reason to believe the new formula can accomplish. At the best its practicable range of use seems to be far more limited than will be generally believed.

Dental groups may be counted upon for authoritative statements as quickly as the formula and technic for its use are adequately checked.

"The Great Destroyer of Life"—Under this title, Dr. J. D. Dowling, Health Officer, Jefferson County Board of Health, broadcast over Station WAPI, on January 16, 1936.

The significance of this event is the fact that in a 3 page talk, "syphilis" or "syphilitic" was mentioned 19 times, and "venereal" 4 times. Not once was "social disease" mentioned. "Ethical morality" and improvement of "the ethical and physical fiber of mankind" were advocated as well as medical prophylaxis.

The presentation was devastating in its picture of widespread significance of the disease.

Misrepresenting a Public Health Situation—Does not "social diseases" imply a moral rather than a public health problem?

When public health workers use the term are they handicapping a public health attack upon disease?

Writing for Listeners—Nine years of experience with one type of daily program is the background for an article on "Writing for Listeners," by H. C. Douglass. *Journal of Home Economics*, Mills Bldg., Washington, D. C. Nov., 1935. *30 cents*. Although written in terms of home economics our readers may readily broaden the application of several quotations:

> First, about selecting a topic. In general, a good rule seems to be to choose a small, specific subject rather than a broad, general one. The human mind can hold only so many ideas at a time, and its capacity is considerably cut when it is already partly taken up with the baby and the broom. Most effective radio talks are appetizers rather than full meals. They don't satiate the listener with so many nourishing facts that none has flavor; rather, they serve up one zestful bit of information that makes the

* Please address questions, samples of printed matter, criticism of anything which appears herein, etc., to Evart G. Routzahn, 130 East 22d St., New York, N. Y.

listener want to taste more. For example, a talk on modern scientific methods of canning is less likely to hold interest than one on the safe canning of the corn ready in the garden. The listener who finds this small definite piece of canning information valuable will want more when her other vegetables are ready to can.

As for the writing of the talk, no hard and fast rules exist, except the general rules of all good writing. A clear, pleasant, enthusiastic voice will often make dull script go over fairly well. But anyone who has the job of preparing radio talks for the average voice soon finds little writing tricks that make any talk more effective.

The style that has proved most successful over the air is simple, natural, and conversational, no matter how scientific the subject. That means simple, familiar words with the fewest possible technical terms, and it means short, easy, straight-forward sentences.

Just why so many home economics speakers avoid this simple style is a question. Radio managers say that scientists and teachers generally don't make interesting talks if left to their own devices. The scientist in front of the microphone is likely to talk as if he were addressing a learned scientific meeting, and the teacher as if she were in the classroom instructing the ignorant young. In fact, one well known radio director declared some time ago that it was easier to get a good talk over the air from a cowboy or a backwoodsman than a Ph.D. People without the so-called higher education often are able to express themselves more naturally and colorfully than those of us whose vocabulary has been changed by scientific and educational training. An unschooled person often knows all the tricks of good story telling and also knows how to use words to build a clear picture for his listeners. The village gossip talking over the back fence about the house-cleaning demonstration may give her neighbor a better picture of house-cleaning methods than the specialist herself could if she had only words to rely on.

When writing a radio talk one

. . . needs to come out of the laboratory and classroom and imagine that she is on her neighbor's porch just talking. She may have news to report, a story to tell, or advice to give. As a radio speaker she is a guest in her listener's home, and she must be a welcome guest if she wants to stay there long enough to finish her conversation. So she takes pains to make her talk interesting, cheerful, sympathetic, and not too long-winded.

Straight-forward statements help to hold attention.

The scientist or the textbook may say, "The study was made," but the radio writer will say, "I made it" or "We made it," or "She made it."

The first paragraph must win the listener.

The tendency in writing this paragraph is to make a formal introduction with a lot of vague generalizations on all phases of the subject—to beat around the bush instead of plunging in. This kind of a first paragraph is ideal for driving listeners away. A good start may be a bit of lively news or an anecdote or some quip to put the listener in good humor, or simply a statement of what the topic is and perhaps also why it was chosen. The important point is to catch the listener's interest. Then, the succeeding paragraphs develop the topic.

A usable reading list accompanies the article.

"Photographs Please!" — Thus pleads N.O.P.H.N. which has received numerous requests for photographs from writers, editors, visiting nurse associations, and other groups.

It has not been possible to keep an up-to-date, attractive supply of photographs on hand. Yet to represent public health nursing pictorially in an adequate way is surely a responsibility of the N.O.P.H.N. and it disturbs us when we are unable to fill requests and to know that the picture of the nurse that is finally published for nation-wide distribution may be totally wrong—a nurse in white, a nurse in high heels, a nurse sitting on the patient's bed, a nurse in uniform—smoking—all of which we have seen recently.

Will you share your pictures?

If you have any clear, glossy prints of the public health nurse at work—in office, home, clinic, school, industry, or just "on the way" in city or country, may we have a copy? If it is a picture we can use and if you have gone to any expense in getting an extra copy for us, we will gladly pay for it, and we will publish the names of contributors to this cause! With the picture will you please send us the following information:

(1) May we use the picture for publicity

purpose without credit to your organization? If not, how do you want the credit line to read?

(2) May we cut off some of the picture if only a part of it is needed?

(3) Is there a charge for the picture?

(4) Has the picture been used in any newspaper or magazine of wide circulation? If so, permission to use it must be obtained from the publisher.

Please send your pictures to the National Organization for Public Health Nursing, 50 West 50th St., New York, N. Y.

We quote all this because it applies equally to all phases of public health. *Much additional national as well as local space for public health topics could be secured if state and local agencies would send photographs to the nationals.* Acceptable photographs would float many a useful article. Many photographs could be used with captions only.

And numerous photographs could be used in other cities in place of local pictures. Of course, in such cases the users will carefully avoid giving any impression except that the photographs are typical of local people or conditions.

If you happen to have a photograph and you do not know where it would be useful, please mail to editor of this department who will pass it on to good advantage.

Please note the four items of information requested by N.O.P.H.N. We would add two requests for information:

(5) Can you supply additional prints (preferably glossy and unmounted)?

(6) Please give all the explanatory detail possible for each photograph.

A Tabloid Presents Venereal Diseases—The *Daily News* of New York City, with the largest newspaper circulation in North America, ran 4 full page articles on v.d. in the first week of February. Here are sample headings:

PARASITES OF MEDICINE. *Charlatans Prey on Seekers of Health.* Quackery is exposed in today's story on venereal diseases. It also frankly discusses prevention, symptoms, and treatment.

MAYOR AIDS DISEASE DRIVE. *City to Launch Anti-Venereal Campaign.* What is New York City doing to combat venereal diseases?

Here are the lead paragraphs of the first and last of the articles.

While you read this sentence more than one million men, women and children in New York City are suffering from venereal diseases. Syphilis infects about 378,000, and gonorrhea twice as many. The nation's victims total at least 19,000,000, or 15 per cent of the population.

Mayor LaGuardia sounded the call to arms yesterday for a conquest of syphilis and gonorrhea. In curt, steel-edged words he called on New Yorkers to mobilize for a city-wide anti-venereal disease crusade led by the Department of Health.

Millions for Health Education—Millions of pieces of printed matter were distributed by tuberculosis associations in 1935.

Exclusive of the Christmas Seal Sale the National Tuberculosis Association published 4,125,454 pieces at a cost of $23,501.07. Excluding 1,600,000,000 seals, the supplies for the Seal Sale totaled an additional 22,645,728 pieces, and the total cost was $112,905.93.

The publications included one book, 5,238 copies; 8 monographs, 22,030 copies; 9 pamphlets, 262,595 copies; 21 circulars, 660,672 copies; 32 reprints, 63,546 copies; 31 miscellaneous and unclassified publications, 219,171 copies; and 12 different Early Diagnosis Campaign publications, a total of 2,892,159 copies.

Not included above are the *American Review of Tuberculosis*, the *Tuberculosis Abstracts*, the monthly *Bulletin*, the *Journal of the Outdoor Life*, the monthly *News Letter* and the annual volume of *Transactions*.

Pasteur on the Screen—"The Story of Louis Pasteur," produced by Warner Brothers, is reviewed by Frank S. Nugent in *New York Times*. Feb.

10, 1936. The *Times* can be found in many public and college libraries.

The dramatic department of the *Times* confesses to heresy. As Mr. Nugent says:

> It believes that accuracy is not the most important part of biography. It will accept errors of time and place cheerfully, and it will condone the addition of known fiction to known fact provided these untruths are committed in the interests of a greater truth, which would be the preservation of spirit—not the chronological letter—of a man's life.
>
> "The Story of Louis Pasteur" telescopes the French scientist's years and highlights his achievements. It embroils him in a prolonged feud with the French Academy of Sciences and its president. It has him incur Napoleon III's displeasure and virtual banishment from Paris. It delays his recognition until the evening of his life. It portrays him as a model of scientific detachment, the laboratory method personified, a modest, academic, self-effacing man.
>
> Most, if not all, of this is against the weight of such biographical evidence as one might encounter in staid Britannica or in the more lively pages of Paul De Kruif. And yet, possibly because we have heretical notions, we believe that Warners' "The Story of Louis Pasteur" is an excellent biography, just as it is a notable photoplay, dignified in subject, dramatic in treatment, and brilliantly played by Paul Muni, Fritz Leiber, Josephine Hutchinson, and many other members of the cast.

Advising versus Educating—For a full perspective read "The Nurse's Opportunity to Teach Parents," by W. Rand. *Public Health Nursing,* 50 W. 50th St., New York, N. Y. Nov., 1935. *35 cents.* But here is set forth the difference between advising and educating.

> It is easy for the nurse to give advice; it is much less easy for the nurse to teach. "You ought to bring your baby to the clinic, Mrs. Brown, to see the doctor." Quickly said, often *not* acted upon, perhaps many times acted upon because a personal relationship, valuable in many ways, has been established between the nurse and Mrs. Brown. Mrs. Brown brings the baby to the clinic because she likes the nurse and wants to please her, although she may not continue to do it when the nurse moves to another district. But is that education? No, that in itself is not education although it may be a first step, for education may result from the experience of the clinic and later contacts. Much less easy, more time consuming even, is it to give uneducated Mrs. Brown some understanding of what the clinic may mean for her and her baby. There must be the marshalling together of facts which the nurse has and which perhaps are only available to Mrs. Brown through the nurse, and the presenting of them in such a way that Mrs. Brown understands them and realizes that they apply to her and her baby, that they are of real significance to *her.* Conviction which leads to action is not just an intellectual process. There is something of an emotional coloring, a feeling tone which is a necessary part of the process and must not be ignored. One can intellectually agree to the reasons why adequate rest is important but one will not take adequate rest until one *feels* one needs it, until the intellectual process has taken on that emotional coloring which means a result in action.

"To Contact" or Not "to Contact"—Shall we contact people, or shall we use a verb which is accepted as such by dictionaries and grammarians?

Shall we write and speak English according to the rules, *following* the crowd only when by crowd usage a noun has become a verb as well?

Or shall we speak and write according to our own convenience, whether or not English purists agree with some of our usage?

School Lunches in Massachusetts—In that state the Federation of Women's Clubs, Red Cross chapters, Selectmen's Association, Consumer's League, American Legion, Boy Scouts (note the range of the coöperating groups), as well as the Departments of Education and Extension, have worked with the Department of Health on a school lunch survey, and the improvement of school lunches in the state.

What was done and much of what

was accomplished is reported in "The School Lunch Survey in Massachusetts," by H. I. Duff, in *Journal of Home Economics*, Mills Bldg., Washington, D. C. Nov., 1935. *30 cents.*

Among the contributory services were panel discussions of selected groups in Boston and in Springfield. A week's summer conference on management was held.

During the last year the Department of Public Health has sent out various bulletins, papers, posters, and other lunchroom helps for teachers, lunchroom managers, school principals and superintendents, nurses, and community organizations. It has also arranged for radio talks and newspaper and magazine articles to increase general interest in and understanding of the school lunch program.

Teaching the Tb. Patient—This is the subject of *Tuberculosis Abstracts* for March, 1936.

When the doctor secures the admission of his patient to a sanatorium his primary object is to secure optimum conditions under which the repair of the damaged lung may be effected. But he has every right to expect also that the sanatorium perform another function which is sometimes overlooked or done in a perfunctory manner, namely, education of the patient. The following abstract of a paper, originally addressed to sanatorium physicians and their staffs, will interest also the general practitioner.

" . . . the superintendent of the sanatorium should be, in effect, educator as well as doctor. Every one of his assistants, nurses, orderlies, and servants is a teacher under his supervision and shares with him the responsibility.

What should the tuberculous patient be taught? His curriculum might be divided into three main groups: (1) a way of life, (2) an understanding of tuberculosis, particularly *his* tuberculosis, and, (3) knowledge of how to protect others."

Dr. H. E. Kleinschmidt, the author, says:

The third broad grouping of the patient's training has to do with the prevention of the spread of his disease. Furnishing a patient with a sputum cup and installing an incinerator may be the alpha of prophylaxis, but it is not the omega. He should learn of course why such scrupulous attention is paid to sputum disposal. But he should learn also the numerous ways in which tubercle bacilli migrate from one person to another. He should develop automatic habits of safety—something akin to the surgeon's "aseptic conscience." To learn by rote that kissing, spitting, the use of common eating utensils, etc., are "verboten," as well but not enough.

It is better to teach simply and clearly the general biology of the disease, the manner in which the germ gets from one person to another, and how it does its deadly work. Give the average person an understanding background and a few specific examples, and he will, himself, regulate his conduct to the best interests of others and his own good.

From an understanding of his own tuberculosis and the desire to avoid infecting his loved ones and friends, is but a short step to the cultivation of an interest in the larger problem of combating the pandemic, tuberculosis. Every patient who leaves the sanatorium should have a good grasp of the broad epidemiologic picture of tuberculosis. The graduate of a sanatorium should be a crusader striking his blows in season and out of season. In him burns an everlasting fire. There are thousands like him. Against the cumulative effect of such force the old, old enemy is bound sooner or later to crumble.

For a copy apply to any tuberculosis association.

Need for Education: Baltimore Speaking—The occasional use of polluted water for drinking purposes is one illustration of the following statement in *Baltimore Health News* (Oct., 1935):

In each community there are certain health hazards which cannot be readily controlled or eliminated by the health department, but which can be avoided by the citizens themselves providing the dangers have been pointed out. If the public understands and coöperates in taking the precautions that may be necessary, those menaces which are less amenable to health department control can be mitigated to a far greater extent than is otherwise possible. Public health education or teaching the lessons of how to keep well is thus a vital function of the health department which should seek by all possible means to teach the public how to guard against health dangers.

Need for Education: North Carolina Speaking—Fantastic "cures" are described in *Health Bulletin,* North Carolina State Board of Health (Sept., 1935), with this statement by the editor:

In the recent epidemic of infantile paralysis, or poliomyelitis, the officials of the State Board of Health have learned a good many things. Some fundamental scientific facts were reëmphasized and stressed anew, and some old fakes which have been operating for many years took on new life. Out of it all one thing seems clear, and that is, the need for better scientific education in the high schools of the state on such matters of everyday importance as the prevention and the spread of disease, also the great need for a better informed public and a more discriminating one when it comes to appraising the value of the thousand and one remedies offered for the most part by people who are totally ignorant of the diseases for which they have cock-sure cures.

Same Slogan, But Different Emphasis—The 1936 Early Diagnosis Campaign of the tuberculosis associations will repeat the slogan of last year: "Fight tuberculosis with modern weapons." Last year the "weapons" discussed were the elements in treatment. In 1936 the presentation will return to early diagnosis as a chief weapon.

We shall retell it with a new inflection and emphasis, and we shall include in our story what is not yet generally known, namely, that the doctor today is able, because of modern weapons, such as the X-ray, to be more precise in his diagnosis than was formerly the case.

A second aspect of the theme to be developed will be that of anticipating tuberculosis before any symptoms appear. To go to the doctor promptly because of a cough that hangs on, loss of weight, or fatigue, is good; to go to him before these evidences of actual danger appear is still better. It pushes the fight back nearer to its source. Modern weapons, such as the tuberculin test and the X-ray, together with modern ways of using these weapons practically and economically must be made known to, and accepted by, the people if we are to clinch the fight. Tuberculosis is still the chief cause of death in the productive period of life—15 to 45. Routine search for early symptomless tuberculosis among students of colleges and high schools and among young people in industry, is the key to the attack in this sector. In this campaign we wish to make the procedure of routine examination with the tuberculin test and X-rays known to parents, educational leaders, doctors, and all who are concerned in the welfare of young people.

The Health Education Committee urges that the E.D.C. be considered as an all-year educational project and not limited to 1 month's activity. Plan your campaign carefully now and if possible lay out a calendar schedule.

Folders and pamphlets, posters, and other supplies will be available through the state tuberculosis associations.

The National Tuberculosis Association will, as in previous years, further the campaign through national channels. Articles will be released to national syndicates; magazines will be offered special articles and cuts; national radio broadcasts will be given. Samples of the booklets will be sent to state health officers, together with a letter soliciting coöperation.

The National Association will also furnish, from time to time, mimeographed material consisting of newspaper articles, radio talks, and other aids. Each month, beginning with April and ending with September, such "publicity kits" will be sent to the state association.

The announcement of the campaign advises that states "order with discrimination." Our suggestion is discrimination against use of the newspaper and magazine cut offered for the campaign. It seems to suggest the nightmare of a patient afflicted by aggressive modern weapons.

Contests in Minnesota—First, there was the 1935 Radio High School Public Speaking Contest. This was the fifth annual contest sponsored by the Minnesota Public Health Association, the Woman's Auxiliary of the Minnesota State Medical Association, and Station WCCO, as a part of the Christmas Seal educational campaign.

Local preliminary contests resulted

in 108 high schools each sending a talk for the state contest. Of these, 10 were broadcast over WCCO, and the manuscripts of 13 others received honorable mention.

Second, was the contest for a cover design for *Everybody's Health*, published by the same Minnesota Public Health Association, St. Paul. The 150 entries came largely from schools, although the ages of contestants ranged from 7 to 76 years.

A School Health " Thermometer " —From Celia Moore, Division of Child Hygiene, Texas State Department of Health, Austin, comes a mimeographed description of a device for enlisting teachers and pupils.

An easily made " thermometer " registers group and individual credits which cover minimum essentials in health training and instruction, control of communicable disease, school plant and equipment.

The device and its uses are easy to understand as described in detail.

Massachusetts Cancer Program—This is the title of a new 6 page pamphlet from Massachusetts Department of Public Health, Boston. The program:

Statistical studies; clinics; hospital; education.

The education program is described as follows:

In order to carry out our instructions to disseminate knowledge to every individual in the state a coöperative cancer control committee is either established or is in the process of being established in every one of the more than 350 communities. This committee is composed of a small central group or steering committee, and a larger group contacted directly by the central committee, and finally, every individual in the community. The steering committee is composed of key people who have friendly and vital contacts with every type of group and individual represented in the community—religious, political, labor, foreign, social, fraternal, patriotic, and service. The members of this steering committee contact representatives of every club in the community. These clubs promise to have at least one meeting a year on cancer. A club does not have to have an impressive membership to become corporate in this plan. The small group of 8 or 12 is an ideal size. The group, itself, determines the type of cancer talk it will have. Some groups prefer a formal talk followed by a question period while others prefer the round-table discussion with the physician during which questions are asked. In any case a question period is desirable. It is at these small group conferences where an individual feels free to ask questions about cancer where the real basic educational work is done.

The local physician is the one who is asked to be the teacher in this program because the decline or increase in early detection of cancer is entirely in his hands, because he will obtain more coöperation from his community if it knows exactly what to do in case of early symptoms and what the early symptoms are, because the local physician knows his community, and because it has always been the natural prerogative of the physician to teach.

The accompanying chart shows the organization of a coöperative cancer control committee in a city of 50,000 or over. With some modification, this plan can be extended to include the smaller communities.

Printed matter is offered; radio broadcasts are given at irregular intervals; a monthly bulletin is available to physicians.

Physicians Lecture on Public Health—The sixth annual series of free public health lectures has been given in Cleveland by the Albert Fairchild Holden Foundation and the Academy of Medicine of Cleveland. Topics:

Mentality and crime . . . High blood pressure . . . The relation of teeth to health and appearance . . . The crippled child.

State Department House Organs —House organs or periodical bulletins reach us from 19 states. They are issued weekly, twice a month, monthly, bi-monthly, or quarterly. Printed or

mimeographed, they run from 4 to 40 pages an issue.

The popular printed page sizes are 6 by 9 inches, and 8½ by 11 inches, but there are many differences in looks and in quantity of material carried.

Their functions, as expressed by the contents, are diverse, or in a few cases, not obvious to the outsider.

Massachusetts, Texas, and the Philippines will be mentioned later. We do not receive the bulletins issued by New York, Florida, and possibly others not listed here.

Arizona: " The welfare of the people is the supreme law." The January issue contains a discussion of water analysis, and statistical tables. Monthly, 4 pages.

California: Recent issues have included a leading article: Psittacosis, bodily resistance and lowered vitality, health and government, or coccidioidal granuloma, etc.; weekly morbidity reports; brief official notices, or other health news, or quotations. Weekly, 4 pages.

Connecticut: "For a clean state and a healthy people." January issue contains reports of two radio talks; several official statements; statistical tables; topics of popular broadcasts for the month. Monthly, 20 pages. (32 pages in December.)

Illinois: February 1 issue contained brief articles, based upon state statistics, on hazards to male and female, physical efficiency, smallpox in Illinois, tuberculosis in cattle, babies fared well last year, the cost of safeguarding milk, the enigma of tuberculosis, together with a limited mortality table. Semi-monthly, 4 pages.

Iowa: The Oct.-Dec. issue is devoted to " The control of tuberculosis in Iowa," covering both the public and the private agency program. Quarterly, 20 pages.

Kentucky: Nearly every issue carries a photograph or cartoon sketch on the cover page. January issue presents infant and preschool child health conferences, social hygiene in the health program, anterior poliomyelitis in Kentucky during 1935, restaurant pests and their control, typhoid carrier work in Kentucky, along with brief information and news paragraphs. Monthly, 12 pages.

Maryland: February issue is devoted to 1935 mortality reports. Monthly, 8 pages.

Michigan: December issue includes articles reviewing 1935, what mental hygiene has to contribute to the understanding of children, whooping cough (diagnosis and control), index for the year, condensed mortality tables. Monthly, 20 pages.

New Hampshire: January issue covers the need of restriction on excessive drafts of water from lakes and ponds, artificial coloring of oranges, government investigation of manufacture of orange beverage bases, artificial color in orange juice drinks deemed an adulterant, Hinton test for syphilis, statistical report of maternity, infancy and child hygiene, and the quality and selection of toilet tissue. Monthly, 12 pages. (New Hampshire usually gives more attention to food and drink than do other states.)

New Mexico: December includes a brief holiday message, the state director's page, the bureau of child welfare, the rôle of the nurse in communicable disease control (from New York State), district health officers' conference, news items about nurses with magazine references available through the Nursing Bureau Loan Library, the community sanitation program, a letter reporting a piece of local health work, and several news paragraphs. Monthly, 9 pages, mimeographed.

North Carolina: " This Bulletin will be sent free to any citizen of the state upon request." January issue contains material on mental health, gen-

eral hygiene and mental hygiene (11 pages from Iowa bulletin), unavoidable (?) accidents (newspaper editorial), and a statement about early diagnosis and treatment of syphilis. As is usual, a photograph appears on the cover page. Monthly, 16 pages.

Ohio: January 15 issue includes the usual column of brief paragraphs ("The Line O' Light"), chicken pox a differential problem, fads and fancies in diets usually dangerous to follow, broadcast topics for month ahead, scarlet fever control tried through cultures, vitamins are a vital aid in the control of rickets, boy coaster overcome by carbon-monoxide fumes, carbon-monoxide poisoning makes a big jump in Ohio, call issued for papers for state medical meeting, sanitary engineering actions taken in December, several paragraphic fillers. Semi-monthly, 4 pages.

Oregon: Two inside pages give weekly morbidity reports by counties, and two outside pages present objectives of mental hygiene, chicken pox, scarlet fever, or other subject. Weekly, 4 pages, mimeographed.

Pennsylvania: "This journal is free to the people of Pennsylvania. A request to the Editor will bring a copy of this magazine to your home without charge." Nov.-Dec. issue carried an editorial on human hibernation, nutrition-calories-costs, the Health Gnome Says (as usual), the polio problem, what housing means to health, the narcotic problem, the Christmas Seal, Department news, and vital statistics comment. Many illustrations. Bi-monthly, 40 pages.

Tennessee: November issue carried articles on plans for increased immunizations, tuberculosis in Tennessee, and malaria control. Monthly, 4 pages.

West Virginia: January issue has New Year verses, a review of 1935 by Department divisions and bureaus, explanation of new state laboratory ruling, staff changes, state news, quotations from President Roosevelt applicable to health workers, announcements of professional institutes. Monthly, 5 mimeographed legal size sheets unstapled.

Wisconsin: Oct.-Dec. issue included public health strides promised through new state legislation, supervision of well drilling a new state function, new legislation for barbers, hotels, and restaurants, classification and pathogenicity of certain yeast-like fungi with special reference to monilia, industrial waste treatment, CCC camps as body and morale builder, sanitary engineering report, health work among Indians, newspaper editorials quoted, communicable disease mortality comment, quarterly mortality report and informational fillers. Quarterly, 32 pages.

DATES AHEAD

March, 1877: "the first visiting nurse started her rounds to the sick poor."

March 29–April 5: National Negro Health Week. Address: National Negro Health Week, U. S. Public Health Service, Washington, D. C.

April 1, April Fool's Day: An opportunity to remind the public of the many people who fool themselves in health matters?

April 12: "the first dispensary opened its doors in Philadelphia in 1786."

April 15: incorporation of National Child Labor Committee in 1904.

April 25–May 2: National Boys' and Girls' Week. Address: at 35 E. Wacker Drive, Chicago, Ill.

April 26–May 2: Better Homes in America Week. Address: in care of Purdue University, West Lafayette, Ind.

May 1: May Day-Child Health Day. Address: your state department of health.

Detailed suggestions for use of above

dates will be found in "News Almanac for Social Work." Community Chests and Councils, 155 E. 44th St., New York, N. Y. *50 cents.*

NEW

Health Officers News Digest, Public Health Committee of the Cup and Container Institute, 30 Rockefeller Plaza, New York, N. Y. "Readers are frankly warned that this publication is propaganda," says Editor Homer N. Calver. Health workers will wish to see a copy.

RADIO

Usually health workers may secure mimeographed copies of broadcasts via Illinois, Baltimore, Connecticut, and Jefferson County.

American Medical Assn. has been changed from the Blue to the Red network of NBC, via WEAF, and certain additional stations, at 5 P.M., eastern standard time, and Pacific network at 2 P.M., Pacific time. This is a dramatized program with incidental music under the general theme of "Medical Emergencies and How They Are Met." Some of the programs are broadcast on short wave through KDKA, Pittsburgh, over W8XK, 11,870 and 12,210 kilocycles. Recent topics have been:

Common household emergencies . . . Tuberculosis . . . Hunting accident . . . Infantile paralysis . . . Diphtheria . . . Scarlet fever . . . Health of the traveler . . . Pneumonia . . . Little tips on home hygiene . . . Heart disease.

Baltimore City Health Department (Tuesdays):

Figures that talk (vital statistics for 1935) . . . Winter sports, exercise, and keeping well . . . Through a pasteurizing plant with a milk inspector . . . Health and physical education in the public schools.

Connecticut State Dept. of Health (WTIC, Thursdays at 1:25 P.M.):

Focusing on the disease germ (what the laboratory reveals) . . . Pneumonia . . . Reducing health hazards in industry . . . Water pollution and the public health . . . Studying the cancer problem . . . Habits which cause irregular teeth.

Illinois State Dept. of Health (WGN, Mondays; WHFC, Saturdays):

No one need die of tuberculosis . . . A new problem of public health workers (diabetes) . . . The new science of phenotypology in medicine . . . Every man his own quack doctor . . . Yesterday and today in medicine . . . Echoes of world war enemies (trench mouth) . . . Outstanding progress in medicine in 1935 . . . Science progresses in brain knowledge . . . The newer "magic" of medicine and heart disease . . . Health today and tomorrow.

Jefferson County Board of Health, Birmingham (WAPI, Thursdays at 10:15 A.M.):

Bedtime for school children . . . The great destroyer of life (syphilis) . . . On catching a cold.

Minnesota State Medical Assn. (WCCO, Minneapolis and St. Paul, every Monday at 10 A.M.):

Value of colonic irrigations . . . Toothache . . . Diet and health . . . Care of the eyes.

Ohio State Dept. of Health (WOSW, Tuesdays at 2:30 P.M.):

Analysis of the annual occupational disease report . . . Population changes as indicated by vital statistics . . . Scarlet fever.

BOOKS AND REPORTS

Immunology—*By Noble P. Sherwood, Ph.D., M.D. St. Louis: Mosby,* 1935. 600 pp. Price, $6.00.

The book is written for medical students and others of comparable background and has developed from mimeograph forms used in such classes. All of which may account for the practical and usable nature of the material presented. A tremendous lot of information is crowded into a relatively—according to present-day standards—short book. It is information concisely and simply presented and arranged in such a fashion as to enable the reader to make use of it in a minimum period of time.

The 3 opening chapters deal with Infection and Infectious Agents, Host-Parasite Relationship, and Anatomical and Physiological Factors in Infection and Resistance of the Individual. In this section—as in others—definitions are freely given and every effort made to present the facts in a simple manner.

With this background, the chapters which follow treat of inflammation and tissue immunity, humoral and cellular defenses, hypersensitiveness, the mechanisms underlying antigen-antibody reactions, and procedures. There are 4 chapters on antigens—their structure and specificity. A short chapter on colloids gives fundamental information and comes just before the discussion of the mechanism of antigen-antibody reactions, a discussion which must assume some knowledge of colloids and their behavior.

Four chapters on Hypersensitiveness conclude the book and are given this place because it is felt that the "present theories pertaining to the complex problems inherent in allergy" are better understood if preceded by discussions of antigen-antibody reactions in general.

The literature has been thoroughly reviewed, the material sorted and reduced, and only the essential conclusions presented. However, complete references are given at the end of practically all chapters and the original papers may be consulted for more detailed information.

It is altogether a book to be recommended to the medical student or to any other person interested in the subject of immunity. The student will find confusing situations cleared up and it should stimulate him to further knowledge.

The book is printed on good paper and is of convenient size.

ANNA DEAN DULANEY

A Textbook of General Bacteriology—*By Edwin O. Jordan, Ph.D. (11th ed.) Philadelphia: Saunders,* 1935. 825 pp. Price, $6.00.

A book that has reached its 11th edition has given proof of its value, and there remains little to be said about it, either in the way of criticism or of praise.

This latest edition has been entirely reset. A number of the chapters, like those on Immunity, Streptococci, Salmonella, Brucella, Rickettsia and on Spirochetes, have been modified and added to, while the section on The Viruses and Virus Diseases has been practically rewritten.

The author feels that the problem of nomenclature is largely unsettled, and hesitates in his book to use names

that have not won fairly general acceptance. Apart from this it may be said that the book maintains the high standard of previous editions. It is beautifully printed and abundantly illustrated, and will doubtless hold the place it has had for so long as one of our leading American textbooks.

MAZŸCK P. RAVENEL

Reports of the National Quarantine Service. Series V, 1934—*Edited by Wu Lien-Teh and C. Y. Wu. Shanghai: National Quarantine Service,* 1935. 233 pp. Price, $2.00.

The fifth series, or 1934 Reports, of the National Quarantine Service of China is edited by the Director, Wu Lien-teh, and C. Y. Wu, the Senior Quarantine Officer. The reports contain 8 original articles relating principally to plague, cholera, and leprosy, and an address by the Director entitled, "The Private Medical Practitioner in Relation to Public Health" —which are all of general interest. The rest of the book contains Divisional Reports, Branch Station Reports, and a list of personnel, which are of local interest, together with the Special Reports on the new quarantine station at Woosung, the Central Cholera Bureau, and analyses of special investigations of human cases of bubonic plague.

In the first of the original articles Dr. Wu Lien-teh briefly summarizes significant epidemiological features of various plague epidemics which have occurred in North and South China. He observes that pneumonic plague is conspicuous in the North. Bubonic plague in China is thought to be transmitted almost exclusively by the *X. cheopis*. In the South, plague is considered on the wane, but some apprehension is expressed that the development of rapid transportation may enhance the dissemination of plague in North China.

Dr. C. Y. Wu relates the existing data on the prevalence of rat fleas in China. Rather continuous surveys are being conducted in 7 ports and the results lend support to the Madras observations of King and Pandit regarding climatic variations of flea incidence. Charts are presented to demonstrate the seasonal distribution of rat fleas correlated with the occurrence of human plague in China.

Dr. J. W. H. Chun presents an analysis of the cholera problem in China. A review of the more important epidemiological studies made in connection with past cholera epidemics indicates that cholera is endemic in China and that recent epidemics are most likely of domestic origin.

Dr. R. Pollitzer, Microbiologist of the National Quarantine Service of Shanghai, reports observations on the behavior of cholera and cholera-like vibrios in blood and milk media. The cholera-like vibrios were taken from routine samples of drinking water collected in Shanghai and the studies are directed toward revealing their true relationship. The results are chiefly of technical interest in a highly important but as yet an unsolved and perplexing epidemiological problem.

Dr. J. W. H. Chun records an analysis of 37 heat stroke cases which were admitted to the Chinese infectious disease hospital at Shanghai during the June and July, 1934, heat wave when the wet bulb temperature remained above 80° F. for 26 consecutive days. The analysis treats different aspects such as age, sex, symptoms, mortality, methods of treatment, duration of hospitalization, etc.

Dr. F. S. Wong and Dr. C. Y. Wu ably discuss the medical inspection of vessels, including emigrant ships, in China. This is of particular interest to health officers.

Dr. Lee S. Huizenga presents a brief but interesting history of leprosy in China. China has some of the oldest

records of mankind and it is indicated that peaks in leprosy incidence occurred B.C. 5000, 1000, 500 and A.D. 250, 600, 1600 and 1930.

The reports reveal the remarkable growth of the National Quarantine Service, which was organized in 1930, and it appears that the apparently insurmountable economic and other difficulties are being overcome with amazing rapidity. F. A. CARMELIA

Free Medical Care, Socialized Medicine—*Compiled and edited by E. C. Buehler. New York: Noble and Noble,* 1935. 360 pp. Price, $2.00.

This book, compiled by the Directors of Forensics at the University of Kansas, is useful. Apparently the selections are made impartially. On the one hand we have articles by Fishbein, Editor of the *J.A.M.A.*, who we believe represents fairly the attitude of the medical profession in general in opposing socialized medicine. On the other hand, there are articles by Ray Lyman Wilbur, Chairman of the Committee on the Costs of Medical Care, as well as by some of those who were engaged in getting out that report. It will be remembered that the committee split three ways in making their report.

There is an interesting chapter which gives outlines of 25 different forms of socialized medicine already adopted in various parts of the United States and Canada. There is a fairly full collection of the reports and resolutions regarding socialized medicine by the American Medical Association, the American College of Surgeons, the American Dental Association, and both the Majority and Minority Reports by the Committee on the Costs of Medical Care.

The controversies in the ranks of the medical profession over this question seem to be meat for those engaged in forensics in the universities. We need only to recall the debates which are going on throughout this country on the subject. We cannot blink the fact that the subject is engaging the attention of many people in this as well as other countries. As a source book this collection can be recommended. It is well printed and put together.

MAZŸCK P. RAVENEL

The Single Woman and Her Emotional Problems—*By Laura Hutton. Baltimore: Wood,* 1935. 151 pp. Price, $2.00.

This little volume, by a physician at the Institute of Medical Psychology, in London, packs into 147 pages more of intelligent understanding and sympathetic insight into the problems confronting the single woman of today, in England and America at least, than this reviewer has ever seen anywhere. It makes no pretense to discussion of the complicated factors, physical, mental, and social, that lie back of the predicament in which thousands of women in our contemporary civilization find themselves, though enough is given to set the problems in proper perspective and to indicate the author's rich background of knowledge and experience. But it goes straight to the point, and deals with the emotional and psychological problems which develop out of the type of adjustment to life which the single woman, willy-nilly, is forced to make.

The basic problem, says Dr. Hutton, is *loneliness,* of the soul-destroying kind brought about by the frustration of a woman's deepest instincts, and which no amount of congenial work or business and professional associations can assuage. It is *personal* relationships that a woman wants, human beings with whom she can share emotional satisfactions, and it is this need that lies back of the irrational behavior so often exhibited by the single woman in her relations with other people. In a

most illuminating chapter, Dr. Hutton discusses her emotional friendships and the problems to which they give rise. Two following chapters discuss the sexual problems of women and sexual inversion or homosexuality candidly and clearly, in a manner that could give offense to no one, and will certainly be of great help and encouragement to women who are struggling with the situations here considered. A final brief chapter on "Adjustments" pulls the entire discussion together and gives some further constructive suggestions regarding the handling of her problems by the woman herself.

We commend the thoughtful perusal of this book to all intelligent people, whether they are in direct contact with the problems it discusses or not. WINIFRED RICHMOND

Lewis' New Air Conditioning for Comfort—*By Samuel R. Lewis. (2nd ed.) Chicago: Keeney Publishing Co.,* 1935. 277 pp. Price, $2.50.

This is a practical book which should prove very useful to engineers concerned with the design and installation of air conditioning systems, and which, if supplemented by handbooks, periodical literature and catalogs, would provide them with the material needed. It is not a textbook which goes deeply into the underlying theory. Clarity and order are its keynote and tempo. The mathematics required for its use do not go beyond arithmetic and simple algebraic equations.

Diagrams, tables, charts, and numerical working examples are abundant. The use of the psychometric table as being more efficacious than the chart is stressed. Consideration of cooling, humidifying, etc., in relation to heating is maintained while clarifications in their relationships are suggested.

Its contents include air conditioning systems, humidifying and dehumidifying, refrigeration for air conditioning, heat transmission and incidental sources of heat, air supply and distribution, water circulation in heating and cooling systems, examples of heating and cooling commercial buildings and houses, and operating costs.

The volume would have the same kind of function in a public health engineer's library as would a good handbook on plumbing. It is too brief to be an exhaustive treatise but it is a fine outline which condenses a great deal of information not otherwise available in assembled form. CHARLES L. POOL

The Human Foot—*By Dudley J. Morton. New York: Columbia University Press,* 1935. 244 pp. Price, $3.00.

The author has taken a long step forward toward placing the study and treatment of foot imbalance on its proper plane of importance and dignity. This book is a distinct contribution to medical literature. The purpose of the book as clearly stated in its preface is a study to identify and analyze the primary factors of functional disorders of the foot. The study has been carried out in three parts: The Evolution and Development of the Human Foot, The Physiology of the Human Foot, The Functional Disorders of the Human Foot.

Under the heading of evolution and development Morton discusses in a most exhaustive and convincing manner the evolution of the human foot from its earliest beginning in the fish up through the amphibian, reptilian, mammalian and early primate periods to the completely developed human foot as it is today. The material contained in this section of the book indicates that an exhaustive research and investigation has been carried out and the subject matter constitutes the most authoritative presentation of evolutionary data on the foot with which we are acquainted.

Under physiology, the function of the foot, both static and in locomotion, is discussed and the extremely interesting conclusions reached are supported by carefully established facts. The conclusions drawn regarding the part played by the muscles of the leg and foot as supports to the arches of the foot are especially interesting and important since they differ widely from many accepted opinions of today. This section contains a very careful study of the mechanism of the foot in standing, walking, and running.

Functional disorders of the foot are considered from two points of view: structural defects and environmental factors, such as general conditions under which the individual lives, and footwear. Three fundamental structural defects are listed as primary causative factors: (1) Short first metatarsal bones; (2) Posteriorly located sesamoid bones; (3) Hypermobility of the first metatarsal segment. Morton explains most of the imbalance which occurs in the foot on the basis of these structural defects although later he adds a fourth—shortened calf muscles. The chapter on treatment is most suggestive since the methods advocated for correcting or counteracting the effects of structural faults in the foot are based on the basic pathology present as determined by the author's investigation. Foot-wear is adequately discussed and the influence of environmental factors thoughtfully dealt with.

It is impossible in a short review to attempt to indicate the completeness and thoroughness of the study which has been carried out and the importance of the observations made. It may be said, however, that Morton's work has raised the diagnosis and treatment of foot conditions from a plane which has been largely empiric to one with a real physiological basis. Not all orthopedic surgeons may be willing to accept in their entirety the conclusions Morton has arrived at but all can profit from a study of this work. In addition to its technical excellence, the subject matter is clear and well coordinated and makes delightful reading. Typographically the publishers have produced an excellent book with copious illustrations.

FRANK D. DICKSON

Pioneering with the Red Cross—*By Ernest P. Bicknell, Vice-Chairman in Charge of Insular and Foreign Operations, The American Red Cross. New York: Macmillan,* 1935. 281 pp. Price, $2.00.

This is a travel and adventure book in connection with great emergencies which occurred in nearly all parts of the world from the time of the San Francisco Earthquake, 1906, to the getting of American refugees out of Europe with the beginning of the World War in 1914, with many personal anecdotes—amusing, dramatic, and some truly awful. It is a narrative in which the author, who started as a newspaperman, became an early organizer of State Charities in Indiana (1893–1898), then Superintendent of the Bureau of Charities of Chicago (1898–1908), and finally National Director of the American Red Cross. It is a story of intimate personal contacts with presidents, cabinet members, kings, queens, princes and princesses, generals and admirals, great business executives, politicians, noted charity, civic, and religious workers, revolutionary leaders, and outlaws.

A master organizer, in simple and straightforward language, interwoven with many facts and figures, relates great cataclysms, general and personal dangers, the meeting of embarrassing situations, graft, audacious opponents, and oftentimes a misinformed public. He recites in detail how these were faithfully and fearlessly met and overcome or assuaged as befitted the occa-

sion. Operations were carried on, oftentimes almost without funds. Mobs were subdued and their energies shaped to useful ends. Well meaning but foolish or ignorant donors and would-be helpers often proved as great problems as the emergencies.

What could be more embarrassing than to have the millers of Minneapolis send enough flour to San Francisco in 1906 literally to block the avenues of transit and to suffice the inhabitants for 10 years! Or, the case of the Yakima farmer who placed a note in a sack of potatoes (of which that fertile Washington valley sent trainloads to Ohio flood sufferers in 1913), and who received, later, a letter from an irate Cincinnatian who had paid full price for the potatoes on the open market, and to have a great Oregon newspaper get hold of the incident—with all the explanation which had to follow—and yet everything was strictly "according to Hoyle," when the facts became known.

No moving picture ever spun its tale more interestingly, or with better themes or more rapid changes of scene. The mine disaster, the forest fire, the volcano which burst without warning in far away Luzon, border warfare and intimate glimpses of the Madero-Villa revolution, ship disasters, etc., and the parts played by women and nurses, doctors and hospitals, philanthropists and governments, railroads and battleships, and so on without end.

The reader gains a coherent idea of the evolution of the American Red Cross during its formative years and, in the aftermaths of catastrophes, the triumph of case work over stultified relief. The development of the Christmas Seals as a means of funding local and national Red Cross, and especially tuberculosis work, forms an interesting interlude.

We have in this volume the memories of a man who was constantly being "found out" and called to greater responsibilities. A study of the bases upon which he made his decisions is worth any one's time. A suitable index accompanies. EMERY R. HAYHURST

Mother and Baby Care in Pictures—*By Louise Zabriskie, R.N. Philadelphia: Lippincott,* 1935. 196 pp. Price, $1.50.

This highly pictorial book is a new adventure in placing before expectant parents the essentials of prenatal care, preparations for confinement, delivery service, and care of the new-born. It covers a wide range of subject matter from the time of conception through each stage of development into infancy and early childhood.

Each section is profusely and beautifully illustrated. The photographic reproductions could scarcely be improved. The captions and descriptions are so clear that any mother can carry out the details.

There is only one possible objection which might be raised by certain of the medical and nursing profession. That is the series of pictures in Chapter VI, which show in detail the various steps in the delivery. What the reaction of the younger generation, who demand a knowledge of all facts, may be can only be surmised. Their parents and the "old family doctor" certainly would expurgate pages 68–71. But this experimental venture should not prejudice us against the whole book, which is exceedingly well prepared by one who has had a wealth of experience in the whole field of obstetric nursing. RICHARD A. BOLT

Public Health Administration in the United States—*By Wilson G. Smillie. New York: Macmillan,* 1936. 458 pp. Price, $3.50.

"This book is dedicated to the Pioneers of the Modern Public Health Movement in the United States, who in

1872 founded the American Public Health Association and at that first meeting laid the foundation stones on which Public Health Administration in the United States has been built."

Dr. Smillie, an experienced and independent research student in administrative health procedures and their results, and a teacher of distinction at the Harvard School of Public Health, has made convenient for health officers and all others concerned with the practice of this specialty of the medical sciences, a long awaited handbook of current health procedures.

He offers factual description rather than critical analysis of the conduct of health departments in this country, with supplementary comment upon the nonofficial health agencies. He stops short of dealing with international health relations, which some readers will regret.

He is particularly courageous, definite, and satisfying in dealing with the desirability of locating school health supervision under a department of health rather than a department of education.

The book will be useful to many physicians and nurses not members of official or nonofficial health agencies, as well as to teachers, editors, and publicists of a wide variety. References, quotations are well chosen, the contents and index adequate and convenient, the form and matter appropriate for the purpose of the volume.

Dr. Smillie is to be complimented upon his priority in this field in the United States, as well as on the excellence of this first edition.

HAVEN EMERSON

BOOKS RECEIVED

LENGTH OF LIFE: A Study of the Life Table. By Louis I. Dublin and Alfred J. Lotka. New York: Ronald Press, 1936. 400 pp. Price, $5.00.

SOCIAL SECURITY. By Edward H. Ochsner. Chicago: Social Security Press, 1936. 231 pp. Price, $.50.

THE GROWTH AND DISTRIBUTION OF POPULATION. By S. Vere Pearson. New York: Wiley, 1935. 448 pp. Price, $4.00.

CRIME, CHARACTER AND EDUCATION. By Sidney J. Beer, Inglewood, Calif. Author, 1935. 190 pp. Price, $1.00.

LOBAR PNEUMONIA AND SERUM THERAPY. By Frederick T. Lord and Roderick Heffron. New York: Commonwealth Fund, 1936. 91 pp. Price, $1.00.

VITAMINS. IN THEORY AND PRACTICE. By Leslie J. Harris. New York: Macmillan, 1935. 240 pp. Price, $3.00.

YOU MUST EAT MEAT. By Max Ernest Jutte. New York: Putnam, 1936. 164 pp. Price, $2.00.

THE DIAGNOSIS AND TREATMENT OF PULMONARY TUBERCULOSIS. By John B. Hawes and Moses J. Stone. Philadelphia: Lea & Febiger, 1936. 215 pp. Price, $2.75.

PRINCIPLES OF HYGIENE. Revised edition. By Thomas A. Storey. Stanford University Press, 1935. 524 pp. Price, $3.50.

YOUR CHILD IN HEALTH AND IN SICKNESS. By Hugh L. Dwyer. New York: Knopf, 1936. 333 pp. Price, $2.75.

DISEASE AND DESTINY. By Ralph H. Major. New York: Appleton-Century, 1936. 338 pp. Price, $3.50.

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH.D.

Midwifery and the Frontier Nursing Service—Among other interesting facts, a survey of the second series of supervised births reveals no maternal deaths from any causes, in spite of the fact that 193 mothers had puerperal complications during pregnancy, 277 during labor, and 83 during the postpartum period.

ANON. Tenth Annual Report. Quart. Bull., Frontier Nursing Service, 11, 1:13 (Summer), 1935.

More Pro BCG—Health records of Canadian infants vaccinated with BCG are so much more favorable than those of an unvaccinated group that the author is forced to conclude that vaccination must be included as a part of a complete anti-tuberculosis program.

BAUDOUIN, J. A. Vaccination Against Tuberculosis With BCG Vaccine. Canad. Pub. Health J. 27, 1:20 (Jan.), 1936.

Rural Midwifery — Picturing the practice by midwives in a rural Virginia county, this survey is typical of country conditions no doubt. Twelve years of midwife instruction appears to have produced precious little in the way of results.

DANIEL, J. L., and GAFAFER, W. M. The Rural Midwife: Her Social and Economic Background and Her Practices as Observed in Brunswick County, Virginia. Pub. Health Rep. 50, 52:1807 (Dec. 27), 1935.

For Better Public Health—Brief references to historic plagues emphasize the author's point that progress in public hygiene follows advances in medical research when properly trained administrators undertake socially justifiable projects. A fine paper.

DRINKER, C. K. Problems and Progress in Public Health. Pub. Health Nurs. 28, 1:10 (Jan.), 1936.

When Two Can Give Artificial Respiration—For artificial respiration, an arm lift movement carried on by a second operator is suggested as a supplementary mechanism to the prone pressure method. The French navy has already adopted this scheme.

DRINKER, C. K., and SHAW, L. A. A Modification of the Neilson Method of Artificial Respiration. J. Indust. Hyg. 17, 6:243 (Nov.), 1935.

Hearing Life Tick—As physiology, which underlies all of hygiene, is a subject in which most of us are woefully weak, this description of recent studies in the mechanism of protoplasm will prove worth careful reading. Incidentally, it is an excellent example of the possibility of putting into plain English a subject as obtruse as biophysics or physical chemistry.

GRAY, G. W. Machines which Imitate Life. Harper's Magazine, 172, 2:341 (Feb.), 1936.

Mental Health of Mothers—All who care for postpartum patients should be aware of the significance of mental health, the symptoms of deviation, and the help which is needed. This is discussed in detail, points being well illustrated by case stories from a visiting nurse association.

HASTINGS, G. L. Mental Hygiene of the Postpartum Period. Trained Nurse & Hosp. Rev. 95, 6:549 (Dec.), 1935.

Pro State Medicine—An account by a physician of an organiation for medical relief set up in a mid-western county that has reduced cost and improved service to the satisfaction of the patients and physicians.

KNISKERN, P. W. Our Town, M.D. Survey Graphic, 25, 1:34 (Jan.), 1936.

Less Syphilis, More Gonorrhea—Fewer pregnant women with syphilis, reduction in clinic admissions and cases reported, and a similar drop in neurosyphilis lead to the conclusion that the disease really is less prevalent in Massachusetts. Marked increases in reported gonorrhea have occurred during the same 5 year interval.

NELSON, N. A The Decreasing Prevalence of Syphilis in Massachusetts. J.A.M.A. 106, 2:105 (Jan. 11), 1936.

Children of the New-Poor—This distressing paper concludes that those who have been viewing with alarm the increased fertility brought on by dependency have probably been exercising themselves over something that did not happen. Things have come to a pretty pass when a heartless researcher dares to pull the props out from under one of our best birth control platforms!

NOTESTEIN, F. W. The Fertility of Populations Supported by Public Relief. Milbank Memorial Quart. 14, 1:37 (Jan.), 1936.

Effective Syphilis Control at Last—After 20 years of struggle, one health department has been granted increased funds to attempt a real state-wide syphilis control program to provide adequate facilities for diagnosis and treatment, improved case supervision, complete epidemiologic investigation, and professional and public education.

PARRAN, T. Syphilis Control in New York State. Milbank Memorial Quart. 14, 1:57 (Jan.), 1936.

Preparing the Nurse for Parent Education—A discussion of what the nurse needs to know about normal children—their growth and development, and about family and community life, if she is to be prepared for parent education. The use of the nursery school by schools of nursing, and the carrying over of nursery school methods into hospital practice is suggested.

RAND, W. What Constitutes a Preparation for the Nurse in Parent Education. Am. J. Nurs. 35, 12:1176 (Dec.), 1935.

In Praise of Meat—This Arctic explorer tells us that others who have had to live on fresh seal, fish or penguin meat did not suffer from scurvy even when deprived of supposed essential antiscorbutics. Total absence of caries from those who live wholly on meat is definite. Cessation of decay occurs when transferred from a mixed to meat diet. Many other virtues are ascribed to meat.

STEFANSSON, V. Adventures in Diet. Harper's Magazine, 172, 1:178 (Jan.), 1936.

How to Control Venereal Diseases—All essential procedures for a state or local venereal disease control program are set forth briefly in the statement of the recommendations of an eminent committee. Adequate diagnostic and treatment facilities, epidemiologic and educational projects are, of course, included. The plan was pretty generally accepted in principle more than a dozen years ago, but it bears repeating since it appears about to be tried somewhat belatedly at least in one state.

VONDERLEHR, R. A., *et al.* Recommendations for a Venereal Disease Control Program. J.A.M.A. 106, 2:115 (Jan. 11), 1936.

Health and Depression—As would be expected, the food of families upon relief and in the lowest income groups in 1933 was deficient chiefly in milk and vegetables. The caloric values were also inadequate.

WIEHL, D. G. Diets of Low Income Families Surveyed in 1933. Pub. Health Rep. 51, 4:77 (Jan. 24), 1936.

Rural Typhoid Prevention—Thirteen years of a rural typhoid fever vaccination program combined with projects for the improvement of rural sanitation produced a marked improvement in the typhoid case rate with no deaths during the last 5 years. Surrounding areas without adequate health administration enjoyed no such decreases.

WILLIAMS, W. C., and BISHOP, E. L. The Typhoid Control Program and Results in Thirteen Years' Work in Williamson County, Tennessee, 1922–35. Pub. Health Rep. 51, 1:1 (Jan. 3), 1936.

Heated Dust vs. Appetite—That odors have an effect upon human health and comfort is the inescapable conclusion to be drawn from the evidence offered.

WINSLOW, C.-E. A., and HERRINGTON, L. P. The Influence of Odor Upon Appetite. Am. J. Hyg. 23, 1:143 (Jan.), 1936.

ASSOCIATION NEWS

APPLICANTS FOR MEMBERSHIP

The following individuals have applied for membership in the Association. They have requested affiliation with the sections indicated.

Health Officers Section

Robert E. Archibald, M.D., 23 Red Rock St., Lynn, Mass., State District Health Officer
Edgar B. Beaver, M.D., County Health Dept., Gallup, N. Mex., Health Officer, District No. 2
Max Bernstein, M.D., 345 E. 116 St., New York, N. Y., District Health Officer
Arthur I. Blau, M.D., 108 W. 136 St., New York, N. Y., District Health Officer
H. Warren Buckler, M.D., 806 Cathedral St., Baltimore, Md., Director, Division of School Hygiene and District Health Officer
F. Edward Burke, M.D., Wakefield, R. I., Health Officer
Dr. R. Frank Cary, Dawson, Ga., Terrell County Commissioner of Health
Donald G. Evans, M.D., C.P.H., 422 Malden Ave., Seattle, Wash., Director of Child Hygiene, City Health Dept.
William H. Hill, M.D., D.P.H., Calgary, Alta., Canada, Medical Officer of Health
John L. Jones, M.D., Court House, Medina, Ohio, Medina County Health Commissioner
Clarence T. Roome, M.D., 2741 Cuesta Rd., Santa Barbara, Calif., City Health Officer
Richard L. Russell, M.D., P. O. Box 148, Springfield, Mo., Greene County Health Officer
Gilbert E. Seaman, M.D., Winnebago, Wis., Superintendent, Winnebago State Hospital
James P. Sharon, M.D., 610 State Bank Bldg., Fort Dodge, Ia., Director, Venereal Disease Control, Webster County
George H. Zerbst, M.D., Manning, S. C., County Health Officer

Laboratory Section

Howard A. Ball, M.D., San Diego County Hospital, San Diego, Calif., Director of Laboratory
Kathryn Barron, B.S., Braden Castle, Manatee, Fla.
Kenneth P. Cash, B.S., City Hall, Lawton, Okla., Health Officer and Chemist
Rolland D. Fox, B.S., 703 Municipal Bldg., Akron, O., Director of Health Dept. Laboratories
Hazel B. Gillespie, B.S., 310 Cedar St., New Haven, Conn., Brady Laboratory
David W. Horn, Ph.D., P. O. Box 666, Bryn Mawr, Pa., Chemist to local suburban boards
C. William Janson, M.A., Cross Highway, Westport, Conn., Director, Diagnostic Bacteriological Laboratory
Einar Leifson, Ph.D., Department of Pathology, Johns Hopkins Medical School, Baltimore, Md., Instructor in Bacteriology

Marian G. Sprick, B.S., 442 Sinclair Ave., N.E., Grand Rapids, Mich., Bacteriologist, Pertussis Immunization Project, Michigan Dept. of Health

Vital Statistics Section

Martin B. Woodward, M.D., State Board of Health, Columbia, S. C., Director of Bureau of Vital Statistics

Public Health Engineering Section

William G. Christy, M.E., Court House, Jersey City, N. J., Smoke Abatement Engineer, Hudson County

Lloyd K. Clark, B.S., State Health Dept., Bismarck, N. D., Sanitary Program, U. S. Public Health Service

H. A. Nordquist, Hobart Mfg. Co., Troy, Ohio, Development of Effective Methods of Cleansing Tableware

Industrial Hygiene Section

James M. Carlisle, M.D., Merck & Co., Inc., Rahway, N. J., Industrial Medicine and Hygiene

Samuel Kahn, M.D., 30 Beekman Place, New York, N. Y., Medical Examiner, New York State Labor Dept.

Charles S. Slocombe, Ph.D., 29 West 39 St., New York, N. Y., Personnel Research Federation

Paul F. Stricker, U. S. Dept. of Labor, Washington, D. C., Safety Engineer, Division of Labor Standards

Food and Nutrition Section

R. Hugh MacDonnell, B.S., 420 Lexington Ave., New York, N. Y., Head of Central Laboratory, Quaker Maid Company

Ira A. Manville, M.D., Ph.D., 7208–34 Ave. S.W., Multnomah, Ore.

William H. Stoner, M.D., Burroughs Wellcome & Co., Tuckahoe, N. Y., Research Consultant

Public Health Education Section

Dorothea Campbell, State Health Dept., Charleston, W. Va., Director, Bureau of Public Health Education

Albert E. Fossier, M.D., 1208 Maison Blanche Bldg., New Orleans, La., Bureau of Medical Education, City Board of Health

Bertha S. Mason, M.D., 82 S. 17 St., San Jose, Calif., College and School Health Work

James G. Stone, 122 E. 7 St., Los Angeles, Calif., Executive Secretary, Los Angeles Tuberculosis and Health Assn.

Elbert W. Wright, M.D., Bowie Clinic, Bowie, Tex., Chairman, State Board of Health

Public Health Nursing Section

Mary Bedford, R.N., Gibson County Health Dept., Trenton, Tenn., Supervising Nurse

Ellen Coffey, R.N., 2849a Accomac St., St. Louis, Mo., Staff Nurse, Municipal Visiting Nurses

Loretta W. Converse, R.N., 63 Dutton Ave., San Leandro, Calif., School Nurse

Laura A. Murphy, R.N., 539 E. 9 St., Erie, Pa., Supervisor of Tuberculosis, Erie Visiting Nurse Assn.

Marian G. Randall, 40 Wall St., New York, N. Y., Technical Staff Member, Division of Research, Milbank Memorial Fund

Mariana H. Ward, R.N., 17 E. 37, Savannah, Ga., Visiting Nursing Supervisor, Savannah Health Center

Epidemiology Section

Martin R. Beyer, M.D., 2006 N.W. 39 St., Oklahoma City, Okla., State Epidemiologist

William R. Carroll, Ph.D., Bacteriology Department, University of Florida, Gainesville, Fla., Professor of Bacteriology and Immunology

Leonard A. Dewey, M.D., C.P.H., Portales, N. Mex., District Health Officer

Lynne A. Fullerton, M.D., 404 Federal Bldg., Spokane, Wash., District Medical Officer, Indian Service

Gerald E. McDaniel, M.D., C.P.H., State Board of Health, Columbia, S. C., Epidemiologist

James D. Trask, M.D., New Haven Hospital, New Haven, Conn., Associate Professor of Pediatrics, Yale University School of Medicine

Unaffiliated

Wendy Stewart, M.D., 445 S. Kingsley Drive, Los Angeles, Calif., Teaching Course in Public Health Law, University of Southern California, School of Government

Barta Wold, R.N., 143 W. 4 St., Williamsport, Pa., Executive Secretary, Lycoming County Tuberculosis Society.

NEWS FROM THE FIELD

FLOATING OF OYSTERS

THE recent action of the New Jersey Health and Sanitary Association Council on a matter of large public importance to New Jersey, draws attention to a very important subject in connection with the public health. The New Jersey association called a spade a spade.

A serious situation of the shellfish industry of New Jersey has grown out of a recent ruling by the U. S. Public Health Service barring from interstate traffic all shellfish originating in New Jersey. This ruling was occasioned by the action on January 14 of the New Jersey State Board of Health, permitting the "floating" of oysters in the Maurice River in South Jersey. This action of the Board of Health rescinded an order against the "floating" of oysters in this river about 2 years ago, based on the accepted fact that the river was polluted and that such a practice was a danger to health.

In announcing the action of the Public Health Service, it has been stated that "The reopening of the Maurice River area has caused the Public Health Service to feel that it cannot consistently continue to give its endorsement to sanitary control of the shellfish industry maintained by the state authorities in New Jersey." This brings the shellfish producers of New Jersey face to face with a critical situation, particularly since the ruling almost automatically prevents domestic as well as interstate sales.

According to the findings of the New Jersey Health and Sanitary Association, the present difficulty arises because of policies which in recent years have governed appointments to the State Board of Health. These appointments have recently been made in some cases from representatives of industrial, commercial, and agricultural interests, who may not be entirely free to ignore the effects that rulings and regulations of the State Department of Health may have on their particular enterprises.

Without questioning the integrity and intelligence of those who are members of the State Board of Health, the local association expresses its conviction that no person should serve as a member if the individual interests of that person may come into conflict with his official responsibility and his duty toward safeguarding the public health. It is their opinion that the shellfish representative now on the Board was placed there to protect the industry rather than to protect the public.

This action in New Jersey appears to be an example of what state associations may accomplish when they take their responsibilities seriously. It is a matter of record that other representatives of commercial interests have been appointed to places of responsibility in various communities, presumably with the purpose of preventing certain actions which may be in the interests of the public health. Fortunately in this instance the Public Health Service is in a strategic position and can properly hold the whip hand. It would be safe to surmise that the shellfish representative on the New Jersey State Board of Health now sees his position in a new light.

NOTE: It is gratifying to learn that on February 11 the New Jersey State Board of Health rescinded its resolution permitting storage of shellfish in the Maurice River and that the federal ban was raised on February 14 for other shellfish from New Jersey.

NEW YORK STATE SEWAGE WORKS ASSOCIATION MEETING

THE Eighth Annual Meeting of the New York State Sewage Works Association was held in New York City, January 14 to 17, with headquarters at the Hotel Astor.

Linn H. Enslow, of New York, F.A.P.H.A., was elected President, and Charles C. Agar, of Albany, Vice-President. Arthur S. Bedell, of the New York State Department of Health, Albany, member A.P.H.A., was reappointed Secretary-Treasurer.

One feature of the program was the presentation, by President Morris M. Cohn, of Schenectady, member A.P.H.A., of the Kenneth Allen Memorial Awards for 1935 to Samuel I. Zack for the most meritorious paper of a technical and research nature, and to Harry H. Hendon, of Birmingham, Ala., member A.P.H.A., for the best paper on sewage plant operation presented during the year. Mr. Hendon presented a paper on "Chemical Treatment during 1935 at Birmingham, Ala.," at the afternoon session, supplementing his paper presented at the previous annual meeting. Mr. Zack presented a paper on "Operating Experiences at Perth Amboy, N. J." and the discussion on these two papers was opened by F. W. Gilcreas, of Albany, member A.P.H.A., and Linn H. Enslow.

The spring meeting of the Association will be held at Lido Beach, L. I., early in June.

DR. HUGH S. CUMMING RETIRES AS SURGEON-GENERAL

HUGH S. CUMMING, M.D., Sc.D., LL.D., retired on February 1 from the post of Surgeon-General of the U. S. Public Health Service, in which he has served since 1894. Dr. Cumming's appointment as Surgeon-General dates from 1920; he was nearing the completion of his fourth consecutive term in that capacity.

Dr. Cumming has been a member of the American Public Health Association since 1914 and was made a charter Fellow in 1922. He served the Association as President in 1931.

Among the outstanding advances made by the U. S. Public Health Service during his administration may be listed the completion of the national quarantine system, the inauguration of pre-immigration examinations at American consulates, the establishment of a national leprosarium and a national narcotic farm, and the construction of 8 marine hospitals. The National Institute of Health was also created from the former Hygienic Laboratory during his term.

Dr. Cumming has also been deeply interested in the promotion of international health work and as Vice-President of the Health Section of the League of Nations, as American member of the Office International d'Hygiene Publique, as United States representative of the Pan-American Sanitary Convention, as director of the Pan-American Sanitary Bureau, and as President of the Allied Medical Mission to Poland, he has rendered distinguished service.

YELLOW FEVER VOLUNTEER DIES

THE daily press of February 10 carried news of the death of Levi E. Folk, who was one of those who submitted himself to the bites of mosquitoes in the well known experiments of Walter Reed, in Cuba. He was 66 years old on February 7.

In 1933, when our Association met in Indianapolis and commemorated there the announcement made by Dr. Reed of his discoveries in 1900, Mr. Folk was one of the 4 survivors who attended. He must be remembered as one of the heroic men who risked his life in the demonstration of this great discovery.

A paper found among his effects told the story of his part in the fight.

"When yellow fever appeared amongst the troops at Columbia Barracks, Cuba," the paper said, "the surgeon (Dr. Reed) asked for volunteers to nurse it. I, with several others, volunteered and was at the yellow fever hospital until I left to go to Camp Lazear in the fall of 1900.

"From November 30 to December 19, 1900, I slept in a specially built house (built to keep out the mosquitoes), in which was placed a large quantity of bedding taken from the beds of patients sick with yellow fever in Havana. I did not suffer any ill effects from this experiment. On January 18, 1901, I submitted to mosquito inoculation and contracted yellow fever on January 23, 1901. After my recovery, I was bitten several times by infected mosquitoes to test my immunity. I did not become infected by any of the bites after that one on January 18, 1901."

NURSES CONVENTION

THE Biennial Convention of the American Nurses' Association, the National League of Nursing Education, and the National Organization for Public Health Nursing will be held in Los Angeles, Calif., June 21–26, 1936. The headquarters hotels for the three nursing groups will be as follows: Ambassador—American Nurses' Association, National League of Nursing Education; Biltmore—National Organization for Public Health Nursing.

ROYAL SANITARY INSTITUTE

ON behalf of the American Public Health Association the following cablegram was dispatched to the Royal Sanitary Institute, London, on the announcement of the death of King George.

> The American Public Health Association extends to the Royal Sanitary Institute sincere condolences on the passing of His Majesty King George V.

The following reply has been received by radio from the Royal Sanitary Institute:

> The Council of the Royal Sanitary Institute in special meeting assembled received the message of condolence from the American Public Health Association on the death of His Majesty King George, Patron of the Institute. They tender to the American Public Health Association sincere thanks for their sympathy in the sorrow the Institute shares with the Nation.

The large number of members of the American Public Health Association who are subjects of the British Crown have suffered a special loss which is shared by the entire world.

DAIRY, FOOD, DRUG OFFICIALS TO MEET IN FLORIDA

THE 1936 meeting of the Association of Dairy, Food and Drug Officials of the United States will be held at the Miami Biltmore Hotel, Coral Gables, Florida, November 9–12.

HEALTH WORKERS OF TENNESSEE

THE eighth annual conference of health workers of Tennessee was held January 30 to February 1, with a registration of approximately 250.

A. W. Freeman, M.D., Dean, School of Hygiene and Public Health, Johns Hopkins University, delivered a paper on "Accepted Policies in the Administration of a County Health Department." Another interesting paper was the one on records and reports by W. F. Walker, Dr.P.H., Director, Division of Health Studies, the Commonwealth Fund.

One morning was devoted to different phases of public health education.

J. P. Leake, M.D., Surgeon, U. S. Public Health Service, gave two talks on epidemiology, his subjects being "Our Current Knowledge of Poliomyelitis," and "Futile Gestures versus Sound Procedures in Communicable Disease Control."

Other guest speakers were Pearl McIver, R.N., Martha Eliot, M.D., Clarence L. Scamman, M.D., and W. K. Sharp, Jr., M.D.

The conference also included an inspection of the new quarters of the State Health Department.

ORTHOPEDIC SURGEONS' EXHIBITS

AT the annual meeting of the American Academy of Orthopedic Surgeons, scientific exhibits were presented by 35 representative orthopedic surgeons. The exhibit of Henry H. Kessler, M.D., F.A.P.H.A., which won the Gold Medal Award, was on the "Cineplastic Operation," which deals with a special operation devised to utilize the remaining muscles in an amputation stump to activate an artificial hand. The exhibit consisted of photographs of cases, photographs of the operative procedure, and plaster models, as well as samples of the prosthesis. It also included motion pictures in color of the operation and the end results in several cases.

DR. GRIFFITH EVANS DEAD

THE London Letter of the *J.A.M.A.* for February 1, 1936, reports the death of Dr. Griffith Evans at the age of 100, at his home in Bangor, North Wales. Only a short time ago he celebrated his 100th birthday, at which time the late King George spoke to him by long distance telephone and offered his congratulations. Dr. Evans discovered the Trypanosoma Evansi, the first trypanosome recognized as the cause of a disease.

MOTHER'S DAY MAY 10

MOTHER'S DAY has taken on added significance during the past few years because of the movement to bring to the attention of the nation the needless waste of life of mothers in childbirth and to develop better maternity care.

A special effort is being launched for the sixth time this year through the Maternity Center Association with the keynote: "Early and Adequate Care Reduces the Risks of Motherhood: Father Plays a Leading Rôle."

NEW JERSEY FATHER CONVICTED FOR REFUSING SON'S IMMUNIZATION

THE refusal of a father to allow his 6 year old son to be immunized against diphtheria resulted, on January 28, in the assessment of a fine of $50 and a sentence of 30 days in jail, in the Juvenile Court of Newark, N. J. According to press reports quoting Charles V. Craster, M.D., D.P.H., City Health Officer, this is the first occasion on which this provision of the State Child Welfare Act has been used to compel children to receive diphtheria prevention treatment. This section of the Child Welfare Act of 1915 defines as neglect, ". . . the failure to prevent the performance of an act necessary to a child's physical welfare." The conviction was secured in spite of the fact that argument indicated that there was no law establishing that immunization was necessary to the child's welfare.

INDUSTRIAL HYGIENE LABORATORIES

ON January 1, 1936, the Industrial Hygiene Laboratories of the Chrysler Corporation began operation. These laboratories, located at the Dodge Main Plant of the Chrysler Corporation, in Detroit, are devoted to the study of occupational diseases and their sources, together with other agencies and conditions of work leading to industrial health hazards. The laboratories are under the direction of Dr. Stewart F. Meek, as industrial hygienist, with Dr. Gordon C. Harrold, as chemist. The laboratories have been planned under the direction of Carey P. McCord, M.D., F.A.P.H.A., who remains associated in the capacity of adviser and consultant.

BOOKS FOR PARENTS

FOR the tenth time in as many consecutive years The Parents' Magazine has made an award for the most helpful book of the year for parents. On February 17, publisher George J. Hecht presented the 1935 medal to Dr. Winifred E. Bain, Assistant Professor of Education of Teachers College, Columbia University, for *Parents Look at Modern Education,* published by D. Appleton-Century Company.

OPEN AIR CONGRESS

THERE has been announced for July 18–23, 1936, the Third International Open Air School Congress, to be held at Bielefeld and Hanover, Germany, shortly before the Olympic games at Berlin.

A bulletin of the International Committee on Open Air Schools can be obtained from the General Secretary of the Congress in Bielefeld or through the Assistant Commissioner of the Office of Education, Department of the Interior, Washington.

CATHARTIC TO MIX IN BREAD COSTS $600 FINE

A POWERFUL coal-tar cathartic has no proper place in bread or any other product sold as a food. The Food and Drug Administration regarded phenolphthalein as an adulterant when it was used as an ingredient of what the manufacturer called a "laxative health bread." The federal court at St. Louis, Mo., agreed with the food officials and imposed a $600 fine on the three members of the Bakers' Research Co. who had been selling "Ownen's Viti-Veg" a mixture of flour, bran and between 10 and 12 per cent of phenolphthalein, a coal-tar cathartic. This mixture was recommended to bakers for addition to their regular bread mix. The product was to be marketed as "laxative health bread."

TESTIMONIAL DINNER FOR DR. WILLIAMS

ON January 22 the Baltimore City Medical Society, the School of Hygiene and Public Health of Johns Hopkins University, the Baltimore Association of Commerce and the Maryland Academy of Medicine and Surgery, united in a testimonial dinner at the Southern Hotel in Baltimore, to Dr. Huntington Williams, Commissioner of Health of Baltimore.

More than 200 physicians and others attended this dinner for which Dr. J. M. T. Finney, Sr., was toastmaster, and at which Hon. Howard W. Jackson, Mayor, Dr. Page Edmond for the Association of Commerce, and Dr. Allen W. Freeman for the School of Hygiene and Public Health, were speakers. Particular attention was paid to the fact that under Dr. Williams's administration the Department of Health has won the award for the largest population group in the 1934 City Health Conservation Contest, sponsored by the American Public Health Association in coöperation with the U. S. Chamber of Commerce.

HEART JOURNAL BECOMES MONTHLY

BEGINNING with the January, 1936, issue, the *American Heart Journal* is published monthly, instead of bimonthly as heretofore during the 10 years of its existence.

TUBERCULOSIS PREVENTORIUM FOR CHILDREN OPENED IN ARIZONA

A SCHOOL for children who are predisposed to tuberculosis has been opened in an abandoned Civilian Conservation Corps camp in the desert 15 miles from Tucson, Ariz. The school has been financed with WPA funds, the *New York Times* reported on January 20, and within 30 days will be caring for 150 boys and 212 girls, it is expected. Outdoor exercise, proper diet, rest, and health super-

vision will be combined with school studies. A large proportion of the children are from families of war veterans, it was stated.—*J.A.M.A.*, Feb. 8, 1936, p. 471.

NATIONAL HEALTH COUNCIL ELECTS OFFICERS

THE annual meeting of the National Health Council was held in New York on February 6.

Dr. Donald B. Armstrong was elected President of the Council, to succeed Colonel Theodore Roosevelt, who was relieved because of urgent and multiplying demands upon his time.

General officers elected are:

Vice-President—T. N. Pfeiffer, present incumbent.

Treasurer—Frederick Osborn, present incumbent.

Secretary—Professor Maurice A. Bigelow, of Columbia University.

Members of the Board of Directors elected are as follows:

R. M. Atwater, M.D., American Public Health Association; Colonel H. E. Bullis, National Committee for Mental Hygiene; L. H. Carris, National Society for the Prevention of Blindness; Dorothy Deming, R.N., National Organization for Public Health Nursing; Howard Green, National Committee of Health Council Executives; Kendall Emerson, M.D., National Tuberculosis Association; C. C. Little, Sc.D., American Society for the Control of Cancer; H. M. Marvin, M.D., American Heart Association; S. H. Osborn, M.D., Conference of State and Provincial Health Authorities of North America; William F. Snow, M.D., American Social Hygiene Association; F. N. Sperry, M.D., American Society for the Hard of Hearing.

At Large: George Baehr, M.D., New York Academy of Medicine; S. J. Crumbine, M.D., Formerly American Child Health Association; H. S. Cumming, M.D., U. S. Public Health Service; William DeKleine, M.D., American Red Cross; Louis I. Dublin, Ph.D., American Public Health Association; Livingston Farrand, M.D., President, Cornell University; Homer Folks, New York State Charities Aid Association; A. S. Knight, M.D., National Committee for Mental Hygiene; Colonel Theodore Roosevelt; Ray Lyman Wilbur, M.D., President, Stanford University.

CONFERENCE OF ILLINOIS HEALTH OFFICERS AND PUBLIC HEALTH NURSES

THESE were some of the outstanding thoughts expressed at the Annual Conference of Illinois Health Officers and Public Health Nurses which took place in Springfield, Ill., on December 10 and 11, with more than 500 delegates present:

Serum for the treatment of pneumonia (in appropriate cases) ought to be distributed free by every state department of public health. Immunization against scarlet fever with 5 doses of scarlet fever toxin is both effective and safe. Vaccine, properly prepared and preserved and given in sufficient dosage at the right time, should confer prolonged immunity against whooping cough in a high percentage of susceptible young children. When politicians or broken-down practitioners are employed as health officers there is no hope of providing the people in reasonable measure with the advantages and benefits of preventive medicine. Adequate and efficient public health service is a fine thing for good medical practitioners (as well as the public) but it is hard on the poor ones. School administrators must get it out of their minds that anyone can teach hygiene. A new philosophy concerning public health is taking root in the minds of governmental officials so that within the next 50 years public health work will be regarded as the first duty of government.

RED CROSS COURSES

American National Red Cross Teacher Training Courses for instructors in home hygiene and care of the

sick are held in coöperation with the following:

University of California at Los Angeles—June 27–August 7

Colorado State College, Fort Collins, Colo.—July 11–August 21

University of Minnesota, Minneapolis—June 15–July 26

Peabody College, Nashville, Tenn.—June 8–July 15

Pennsylvania State College, State College, Pa.—June 29–August 7

Syracuse University, Syracuse, N. Y.—July 8–August 14

All communications for information should be addressed to Public Health Nursing and Home Hygiene and Care of the Sick Service:

National Headquarters, American Red Cross, Washington, D. C. (for Eastern Area)

Midwestern Branch, American Red Cross, 1709 Washington Ave., St. Louis, Missouri (for Midwestern Area)

Pacific Branch, American Red Cross, Civic Auditorium, San Francisco, Calif. (for Pacific Area).

PERSONALS

ARTHUR W. HEDRICH, Sc.D., Fellow A.P.H.A., has been appointed Chief of the Vital Statistics Division of the Maryland State Department of Health. Dr. Hedrich has been for some years connected with the Biostatistics Department of the School of Hygiene and Public Health of Johns Hopkins University, Baltimore, Md., and will continue certain teaching in that institution. He fills the vacancy made by the appointment of John Collinson, M.D., D.P.H., F.A.P.H.A., to the position of Assistant Chief Statistician of the U. S. Bureau of the Census, Washington, D. C.

MILTON J. ROSENAU, M.D., F.A.P.H.A., who retired in 1935 as Professor of Preventive Medicine and Hygiene in the Harvard Medical School, Boston, has been appointed as of January 15, 1936, in charge of the Division of Public Health in the University of North Carolina School of Medicine, Chapel Hill. This division will coöperate with the State Board of Health, members of the executive staff of which will form part of the teaching staff.

MORLEY B. BECKETT, M.D., member A.P.H.A., has recently severed his connection with the Michigan State Department of Health in Lansing and become associated with the Kellogg Foundation.

LOUIS V. WALDRON, M.D., member A.P.H.A., has been appointed Commissioner of Health for the city of Yonkers, N. Y., to succeed Dr. William S. Coons, deceased. Dr. Coons served only a few weeks after his appointment in December, 1935.

V. K. VOLK, M.D., F.A.P.H.A., has recently been appointed Commissioner of Health and Medical Director of the County Contagious and Tuberculosis Hospitals in the Saginaw County Department of Health, Saginaw, Mich. Dr. Volk has recently been the Deputy Commissioner of Health of Pontiac, Mich. He began his new responsibilities on February 3.

JULIA GROSCOP, R.N., F.A.P.H.A., has been appointed Regional Public Health Nursing Consultant for the U. S. Public Health Service with offices at Chicago, Ill.

HAROLD S. DIEHL, M.D., member A.P.H.A., Professor and the head of the Department of Preventive Medicine and Public Health in the University of Minnesota Medical School and Graduate School, has recently been appointed Dean of the Medical Sciences.

ELMER V. MCCOLLUM, PH.D., Fellow A.P.H.A., Professor of Biochemistry and Head of the Department at Johns Hopkins University School of

Hygiene and Public Health, Baltimore, Md., has been presented with the Callahan Memorial Award by the Ohio State Dental Society, for his research in nutrition. The award is a gold medal given each year to a person "who has made a contribution to dental science which is of very exceptional value."

WILLIAM H. BRISTOW, of New Cumberland, Pa., has been appointed General Secretary of the National Congress of Parents and Teachers, with offices at 1201 Sixteenth Street, N.W., Washington, D. C.

FLORENCE FALLGATTER has been appointed as Chief of the Home Economics Education Service in the Vocational Home Economics Division, as announced by the Office of Education, U. S. Department of the Interior, Washington, D. C.

CHARLES W. FOLSOM, of Lafayette, Ga., member A.P.H.A., formerly Health Officer, Knox County, Ky., has been appointed to a similar position with the Walker-Catoosa County Health Department, Ga., succeeding Dr. Samuel P. Hall, Jr., who resigned.

ROBERT FRANK CARY, M.D., of Dawson, Ga., F.A.P.H.A., has been elected Health Officer of Terrell County.

HENRY GRADY CALLISON, M.D., of Augusta, Ga., F.A.P.H.A., has been named Health Commissioner of Augusta, and Dr. William A. Mulherin is Chairman of the Board.

DR. WILLIAM C. HUNSICKER has been appointed Director of Health of Philadelphia, and Dr. Alfred F. Allman, Assistant Director.

DOYLE E. HINTON, formerly Executive Secretary of the Delaware Anti-Tuberculosis Society, has been appointed to succeed Arthur J. Strawson as Executive Secretary of the Southern Worcester County Health Association at Worcester, Mass.

DR. IRMEL W. BROWN has been named Director of the Health Department of Kalamazoo, Mich., succeeding John L. Lavan, M.D., F.A.P.H.A., resigned.

WILLIAM H. PICKETT, M.D., of Saginaw, Mich., F.A.P.H.A., has resigned as Health Officer of Saginaw County, to accept a similar position in Florida.

CLARENCE COOK LITTLE, Sc.D., of Bar Harbor, Me., member A.P.H.A., Managing Director of the American Society for the Control of Cancer, has accepted the presidency of the American Birth Control League.

DR. ARCHIBALD BARKLIE COULTER has been appointed Director of the Bureau of Tuberculosis of the Health Department of the District of Columbia on a part-time basis. Dr. Coulter was recently named tuberculosis coördinator of the District.

DR. KARL V. QUINN, of Belchertown, Mass., has been appointed Assistant Commissioner of Mental Diseases for Massachusetts.

DR. SHERMAN S. FRAZIER, of Angola, Ind., has been appointed Secretary of the Angola City Board of Health, to succeed the late Dr. P. Norman Sutherland, who held the position for more than 25 years.

DR. ALVA L. SPINNING, of Covington, Ind., has been appointed Health Officer of Fountain County.

DR. WILLIAM BASIL KEELER, Medical Inspector for the South Boston Health Unit, has been appointed Health Commissioner of Boston, Mass., succeeding the late Dr. Francis X. Mahoney.

DR. HENRY T. DONOVAN has become the new Health Officer of Coffee County, Ala. The establishment

of the health unit in Coffee County makes a total of 57 health units, according to the press, in the State of Alabama, leaving but 10 counties without organized health service. This total of 57 represents a high record for Alabama, although by 1932, 54 counties had been organized. But during the depression 8 of these discontinued full-time service.

DR. JOHN CLIFTON, of Vermillion, Kans., has been appointed Health Officer of Marshall County, succeeding Dr. Charles E. Gaston, of Frankfort, resigned.

DEATHS

DR. JAMES S. WALTON, member A.P.H.A., District Health Officer of the New York State Health Department and former City Health Officer of Amsterdam, N. Y., died on February 19. He was 67 years old. Dr. Walton had practiced in Amsterdam for 35 years.

THEODORE F. FOSTER, M.D., member A.P.H.A., died on February 10. Until his illness a year ago he was Secretary of the Connecticut Public Health Association. Dr. Foster spent 2 years in Russia with the American Relief after the War and 3 years with the Tennessee State Health Department. He was a member of the Delta Omega.

DR. ADOLPH J. PISTOR, Chief of the Meat Inspection Division of the Bureau of Animal Industry, U. S. Department of Agriculture, died January 25, at the age of 59 years.

CONFERENCES AND DATES

Mar. 2–6, Twentieth Annual Session of the American College of Physicians, Detroit, Mich.

Mar. 25–28, American Society of Biological Chemistry, Washington, D. C.

Mar. 25–28, Federation of American Societies for Experimental Biology, Washington, D. C.

Mar. 25–28, American Society for Pharmacology and Experimental Therapeutics, Washington, D. C.

Mar. 29–Apr. 4, National Negro Health Week.

Apr. 1–3, Canadian Section of the American Water Works Association, Hotel Royal Connaught, Hamilton, Ont.

Apr. 8, Annual Meeting of the Massachusetts Tuberculosis League, Hotel Kimball, Springfield, Mass.

Apr. 9–10, American Association of Pathologists and Bacteriologists, Boston, Mass.

Apr. 9–11, American Association of Anatomists, Durham, N. C.

Apr. 15–18, American Physical Education Association Convention, Hotel Statler, St. Louis, Mo.

Apr. 22–25, National Tuberculosis Association, New Orleans, La. Meeting Headquarters, Municipal Auditorium; Residence Headquarters, Hotel Roosevelt.

Apr. 25–May 2, National Boys' and Girls' Week.

May 3–6, International Society for Crippled Children, St. Louis, Mo.

May 10, Mother's Day.

May 11–15, American Medical Association Convention, Kansas City, Mo.

May 11–15, 40th Annual Convention—National Congress of Parents and Teachers, Hotel Schroeder, Milwaukee, Wis.

May 14–16, American Water Works Association—Pacific Northwest Section, Aberdeen, Wash.

June 8–12, Annual Convention of American Water Works Association, Hotel Biltmore, Los Angeles, Calif.

June 10, Spring Meeting of the New York State Sewage Works Association, Lido Beach, L. I., N. Y.

June 21–26, Biennial Convention of the American Nurses' Association, the National League of Nursing Education, and the National Organization for Public Health Nursing, Los Angeles, Calif. Headquarters will be, respectively: A.N.A., and N.L.N.E., Ambassador Hotel; N.O.P.H.N., Biltmore Hotel.

June 22–25, Annual Meeting of the National Association of Master Plumbers, Buffalo, N. Y.

June 24–27, Seventh Annual Meeting, Western Branch, A.P.H.A.—meeting simultaneously with Canadian Public Health Association—Vancouver and Victoria, B. C.

July 6–11, The Royal Sanitary Institute, Southport, England.

July 18–23, Third International Open Air School Congress, Bielefeld and Hanover, Germany.

July 25–Aug. 1, The Second International Congress of Microbiology, London.

Sept. 8–10, International Union Against Tuberculosis, Lisbon, Portugal.

Oct. 12–17, The Dairy Industries Exposition, Atlantic City, N. J.

Oct. 19–22, Sixty-fifth Annual Meeting of the American Public Health Association, New Orleans, La. Meetings Headquarters, Municipal Auditorium; Residence Headquarters, Hotel Roosevelt.

Oct. 29-31, Annual Meeting of the Association of Military Surgeons, Detroit, Mich.

Nov. 9–12, Association of Dairy, Food and Drug Officials of the United States, Miami Biltmore Hotel, Coral Gables, Fla.

July 27–31, 1937 Second International Congress on Mental Hygiene, Paris.

Length of Life

A Study of the Life Table

By Louis I. Dublin, Ph.D., Third Vice President and Statistician; and Alfred J. Lotka, D.Sc., Assistant Statistician, Metropolitan Life Insurance Company

Dr. Dublin

Dr. Lotka

What This Book Covers

- The Life Span, The Life Table, and the Average Length of Life
- The Life Table as a Record of Progress — From Antiquity to the End of the Nineteenth Century
- The Gain in Expectation of Life in the United States in Recent Times
- Geographic Distribution of Longevity in the United States
- Biological Aspects of the Life Table
- The Inheritance of Longevity
- The Contribution of Medical and Sanitary Science to Human Longevity
- Longevity in Relation to Physical Conditions, with Special Reference to Impairments
- Longevity in Relation to Occupation
- Application of the Life Table to Population Problems
- Application of the Life Table to Economic Problems
- Life Tables Based on the Experience of Life Insurance Companies
- Life Table Construction

Important Tables and Charts

Contains a collection of life tables unequalled in any other single source. Includes a set of original life tables for U. S., by color and sex, individual states, urban and rural areas, etc., at time of last census; life tables for important foreign countries; and tables based on mortality among insured persons and annuitants. Also 50 other tables of various types. Over 50 graphic charts illustrate life table characteristics, improvement in mortality, geographic distribution of population increase, etc.

Presents the life table as the living story of the biological and sociological circumstances which determine the course and duration of human life.

LENGTH OF LIFE is a systematic and full presentation of the essential facts available on the subject of human longevity.

The book traces from early times to the present day the lengthening of the average human life. It analyzes longevity in relation to geography, to the separate causes of death, to occupation, to heredity and to many other factors. Special attention is given to the part which modern medicine and sanitation have played in adding some 20 years to the average length of life within relatively recent times. The life table as a scientific measuring rod of longevity is explained and illustrated by examples. It is shown how the life table is applied in studying social and economic phenomena closely related to vital statistics and to problems of population growth. The book contains the most extensive collection of life tables available in any single source.

Throughout, the discussions in Length of Life are clear and understandable. For those technically interested there is a detailed exposition of approved methods for computing life tables.

Hundreds of Questions Answered

How does the average length of life today compare with that of 100 years ago?
How do the several states of the Union rank as regards longevity of their populations?
What is the probability of dying from heart disease? From tuberculosis?
What is the toll of life taken by cancer, diabetes, Bright's disease, etc.?
What is the probable future attainment of longevity?
Where has medical science scored its greatest successes?
What are some outstanding industrial hazards, and are they being reduced?
What age changes are taking place in the American population?
What effects will they have?
How is a life table employed in computing insurance premiums?
How is a life table constructed?
—These are typical of hundreds of interesting and important points discussed in the book.

$5

5 Days' Trial — No Advance Payment

At our risk and without advance payment, you can examine a copy of Length of Life and see its value for yourself before you decide whether to buy it. For five days you can inspect this outstanding book—refer to it for the many answers it gives on questions of public health work—examine its tables and charts. Then decide.

If the book does not far surpass your expectations simply return it. If you keep it, send us \$5.00, plus a few cents for delivery charges, at the end of the five-day approval period.

400 PAGES — 121 TABLES AND CHARTS

IMPORTANT *Facts* ABOUT CHLORINE STERILIZATION

By J. W. YATES

A chlorine solution—to obtain maximum germicidal action, at greatest speed and lowest cost—must meet four necessary requirements:

1 *The Chlorine Must Be Active in the Solution As Used.* This depends, among other things, on the pH of the solution as used. A solution having a low pH contains a greater concentration of hypochlorous acid than one of a high pH; consequently, greater germicidal activity.

2 *Stability of the Solution When Heated.* Chlorine in solution as used should not be destroyed by heat. Heating increases germicidal activity and signifies that the temperatures already being used will not have to be changed because of chlorine being employed.

3 *Time of Exposure.* In most cases, actual contact of the chlorine with the contaminated surface is but a second or two. Quick germicidal action is therefore most important in a chlorine solution.

4 *Value of Chlorine.* The quicker the germicidal action, the less amount of available chlorine needed in solution. Hence, a saving in sterilizing cost.

. . .

B-K and B-K Powder adapt themselves more readily to these four factors than any other chlorine compound on the market. One 28-ounce bottle of B-K Powder costing $1.50 will make 1000 gallons of 100 p.p.m. available chlorine solution of low pH value and this solution is in a most readily active form which can be used in either cold or hot solutions.

Correspondence is invited on your Sanitation and Sterilization Problems.

District Health Administration in Large Cities*

JOHN L. RICE, M.D., F.A.P.H.A., AND
MARGARET W. BARNARD, M.D., DR.P.H., F.A.P.H.A.

Commissioner of Health, and Director of District Health Administration, Department of Health, New York, N. Y.

A PUBLIC health program, to be effective, must be based on an intimate knowledge of the health problems of a given community, and must be adapted to its needs and resources. As a city grows in size and complexity, it becomes increasingly difficult for the health officer to meet these requisites, and some type of regional supervision of public health activities becomes necessary. Localization of clinic services, such as those in the maternity and child hygiene or tuberculosis fields, to reach population groups most in need of them, is an accepted practice. Official health departments in a number of large cities have gone a step further and have organized their resources administratively on a neighborhood or district basis, coöperating with medical societies and nonofficial health and welfare agencies. This makes it possible for the official agency to plan and administer a health program adapted to the particular needs of a given district and coördinated with the work of other agencies in the area.

New York City, with its 7,000,000 people living in an area of over 300 square miles, is an outstanding example of the need for district localization of health services. The enormous heterogeneous population with its varying density, and with its host of localized areas of custom, environment, understanding and thought, presents a challenging problem in effective public health administration and service. Those interested in public health have long recognized the necessity of developing an administrative technic which will point out the needs, resources, and opportunities in the varying sections of the city, and which also will render health work more effective by bringing it closer to the people.

After a number of years of study of the various field experiments and health demonstrations already in operation, New York City has adopted a program of district health administration in which health work eventually will be localized in 30 units of popula-

* Read before the Health Officers Section of the American Public Health Association at the Sixty-fourth Annual Meeting in Milwaukee, Wis., October 7, 1935.

tion of from 200,000 to 250,000. In January, 1934, a Bureau of District Health Administration was established, with a full-time director, and during the year a full-time district health officer was appointed to each of the 7 districts where health needs were greatest. The 7 district programs have been slowly interwoven with the general Health Department program and the health and welfare activities of their communities. Funds for 8 health center buildings have been made available by the Federal Public Works Administration. These buildings, which will be ready in the near future, will provide adequate headquarters and will be an important factor in stabilizing district health work. A typical building will provide space on the ground floor for functional services (maternity and child hygiene, dental, tuberculosis, and venereal disease). On the second floor will be located the administrative unit, Health Department nurses, and a visiting nurse unit. A station for the distribution of departmental supplies and biologicals will be established in the administrative office for the convenience of physicians in the district. On the third floor, in addition to the health education unit, space is provided for coöperating voluntary agencies working in the district. An auditorium in the basement will provide, either a large meeting place for about 250 people or, by subdivision, 3 conference rooms. Medical societies will be offered free use of the building for group or committee meetings, and in some of the centers it is possible to provide a special office for the local medical society in the district. At the request of several of the medical committees, a current health education display of material related to local conditions will be kept in each center.

One of the most important influences in the development of district health administration during the year has been the support and coöperation of the present city administration. Mayor La Guardia has repeatedly indicated his interest in the plan for health centers, and has been instrumental in forwarding the building program.

As the district program has developed, there are becoming increasingly clear certain issues which are presented in this discussion in the light of New York's experience, but which we believe are pertinent to any program of district administration in a large city.

Long Distance Planning and Integration—An effective district program in a city requires the welding into a coördinated program of all the health and welfare activities of the community. To accomplish this there must be long-distance coöperative planning by both the official and voluntary agencies, so that the program, while remaining flexible, may still proceed in a logical manner and not be haphazard or governed primarily by expediency. To accomplish this in New York City, the Committee on Neighborhood Health Development was organized in 1929. This committee, with Dr. Wynne, then Commissioner of Health, as Chairman, and with a permanent director, was composed of the leaders in voluntary and official work in this field in New York City. Under its leadership, a program was formulated for 30 health districts; boundaries were established, not only suited to local demography and activities, but based on permanent census tracts, so that the population data and vital statistics were made available for each area. All pertinent economic, social, and health data are carried currently for each of the 30 districts as a basis for program planning. Further, realizing that even a health center district, with its unit of approximately 200,000 population, may conceal a wide range of health and social conditions of which the District

Health Officer must be aware in order to work effectively, the committee carries currently for the organized districts all health and related data by smaller units, known as "health areas," each with about 25,000 population. This painstaking groundwork is reflected in the intelligent understanding and support of the program by the agencies of the community. Each district, as it is organized, has its own general advisory and medical advisory committees, which function as subcommittees of the Committee on Neighborhood Health Development.

Scope of Localized Services—In establishing a district health program, careful consideration must be given to how far it is practical to go in decentralization and what types of service best lend themselves to this plan. It was decided that for the present in New York City the scope of the district program should be limited to those services which are most clearly related to the people, with emphasis on preventive medicine and health education. The services at present localized include: nursing (including home visiting for contagion); maternity and child hygiene (prenatal, infant, and preschool); school hygiene (school medical inspection, dental, eye, cardiac); tuberculosis; venereal disease; and health education. These function under a local administrative unit, which includes district records and statistics. This leaves the following services which it is believed can for the present be more effectively administered on a city-wide or borough basis: food and drugs; sanitation; laboratories; vital statistics; and the control of communicable diseases.

Reporting of contagion is most easily done on a borough basis, since the borough boundaries are more familiar to most people than are those of the individual health districts. The control of communicable diseases also carries with it a certain amount of police authority. It would seem wise for this to remain, for the present at least, vested in the more impersonal central office. Epidemiology is still being developed and therefore remains a central office function for the present.

Administrative Relationships within the Department—The change from a centralized bureau control, either direct to the field staff or through a borough representative, to the localized administrative responsibility of a District Health Officer, for a program which includes the activities of many bureaus, is fundamental and complex. A tentative organization scheme has been worked out and adopted until experience shall point further changes (Figures I and II—Organization Chart).

The administration of public health work in New York City is the responsibility of the Department of Health, directed by a Commissioner of Health. Details of services are delegated to deputy commissioners of health and to directors of bureaus organized for the conduct of special activities. The Director of the Bureau of District Health Administration reports directly to the Commissioner and is in immediate supervision of the district health officers. All policies are determined by the respective bureau directors, subject to the approval of the Commissioner. It is then the responsibility of the district health officer to administer these policies in his district. The district health officer may not change a policy, but it is his responsibility to evaluate policies in the light of their effectiveness in his district and suggest changes which seem wise. Since the health officer is primarily an administrator and not a specialist in the various services, it is considered best for technical supervision to come directly from the bureau concerned to the field staff. Thus the quality of technical work, training of personnel,

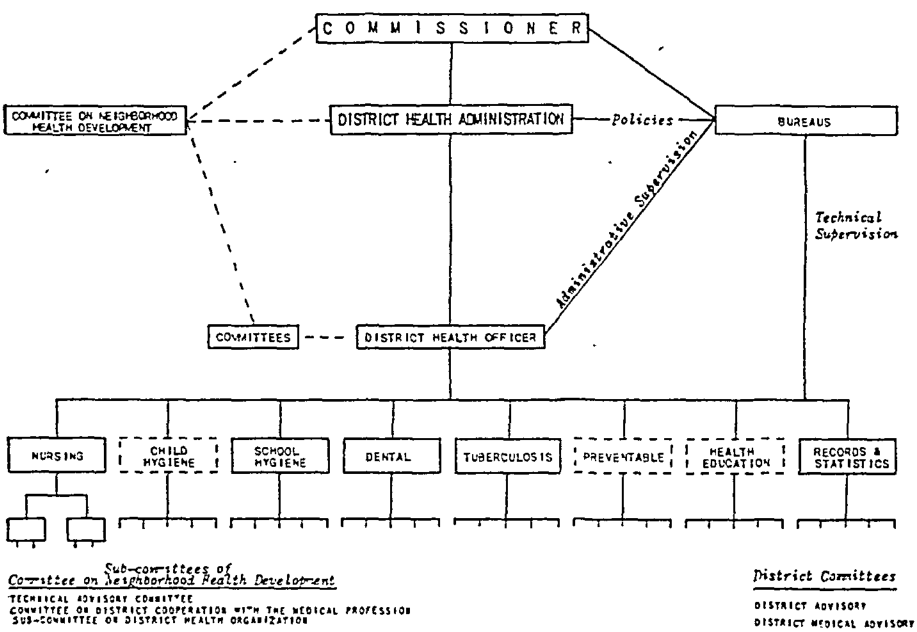
Department of Health, City of New York



and professional standards for any special activity remain the responsibility of the director of that bureau.

The persons in charge of functional services within a district, such as tuberculosis, child hygiene, school hygiene, dental service, and nursing, are associates of the health officer and are responsible to him for the administrative detail of their work. They direct the assistant staff personnel in their functional fields. The district supervising nurse acts also as the assistant to the health officer and in his absence assumes charge of the district health office.

Community Organization — To be productive, a district health program must have the whole hearted support of its community. The medical and dental professions, the voluntary health and welfare agencies, and the civic organizations contribute substantially to the success of the venture.

In the New York City plan, it is the responsibility of the district health officer to give leadership toward such a coördinated community health program, and to furnish the secretariat for the district committees. One of these consists of 10 or 15 private physicians of the district, who serve in an advisory capacity regarding medical policies and program. These physicians are recommended by the County Medical Society and appointed by the Commissioner. They not only advise with the health officer, but are most useful in interpreting the work of the health district to the physicians of the community. Another general advisory committee consists of local representatives in the fields of health and welfare. This group considers how best to coördinate the departmental and voluntary work in the area, and also interprets the work of the health district to the other agencies of the community. The health

FIGURE III

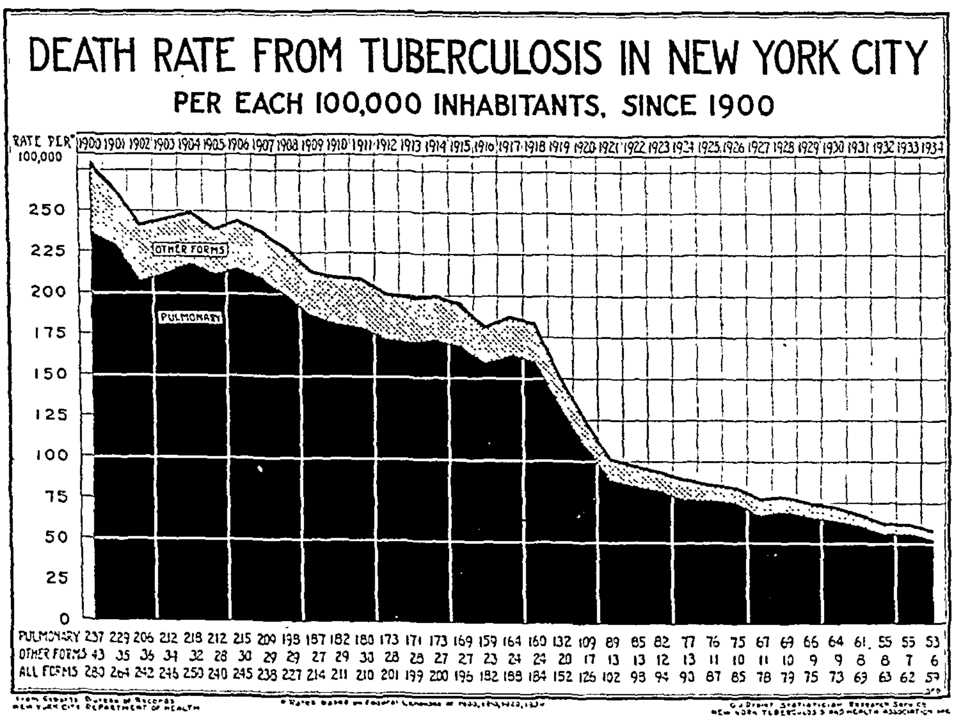


FIGURE IV

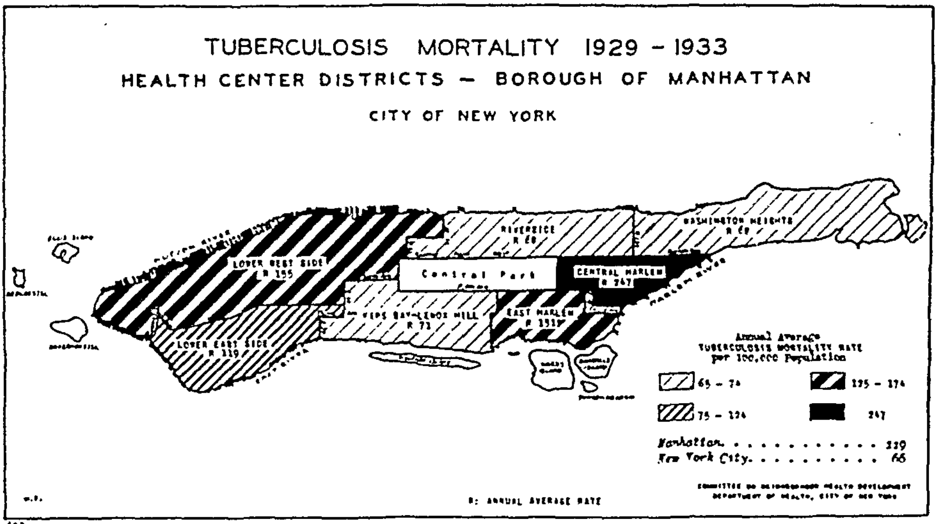


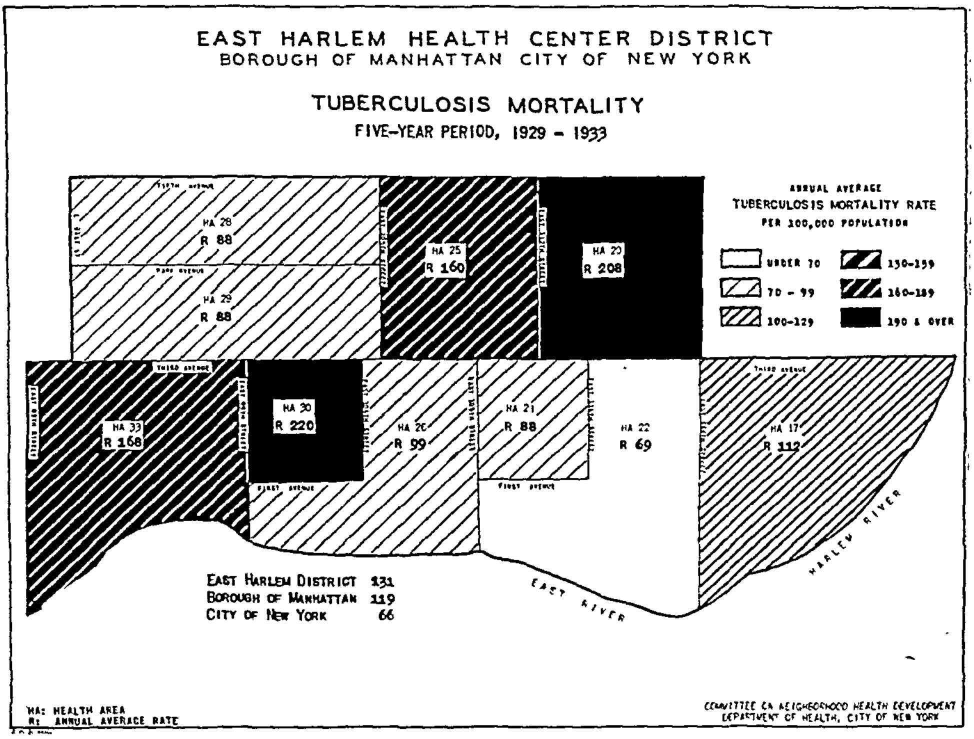
officer takes an active interest in the plans of other agencies by serving on their committees and giving both formal and informal talks to many local groups.

District Statistics and Records—One of the important parts of district work is the analysis of health needs, resources, and work by local areas within the district. Only in this way can the so-called sore spots be detected and work emphasized at those points. The tuberculosis work illustrates this. New York City may well be proud of its steadily declining rates for tuberculosis mortality and morbidity (Figure III—Tuberculosis Mortality Rate—New York City, 1900–1934). However, when these data are broken up by districts, it becomes apparent that the decline is not uniform throughout the city. For example, the tuberculosis mortality rate for the city as a whole, for the period 1929–1933, was 69 per 100,000 population; but, for 3 health districts, was very much higher (Figure IV—Tuberculosis Mortality, 1929–1933, Borough of Manhattan). During this period, the tuberculosis mortality rates were 247 in Central Harlem, 155 in Lower West Side, and 131 in East Harlem. Furthermore, if one of these districts (for example, East Harlem) is further subdivided into its component health areas (Figure V—Tuberculosis Mortality, 1929–1933, East Harlem District), it will be seen that the rate varies from 69 in Health Area 22, where the East Harlem Health Center demonstration has been carried on for the past 14 years, to 208 and 220 in Health Areas 20 and 30 respectively. It is in these latter areas that intensive work in this district is needed. It is also of interest that these areas have the largest proportion of Negro and Puerto Rican population in the district (approximately 28 per cent) and are of the lowest economic level.

Current health data and analysis of services are kept by health areas and health districts as the basis of program planning.

Health Education—As the health officer becomes familiar with his district, the necessity for methods of health education which will meet local needs and be productive of results in a given section becomes apparent.

FIGURE V



Health education, perhaps more than any other service, is effective only as it is adapted to local circumstances. The health officer, with the assistance of the Bureau of Health Education, and in coöperation with the agencies in his district, builds his health education program around the needs and resources of his community.

Opportunities for Research and Demonstration—There is always need for new administrative procedures and technics. In a large city it is much easier if such experiments can be first tried out in a fairly small population group.

If successful, the procedure may, after thorough trial and, often, changes based on experience, be instituted throughout the city. If, on the other hand, the venture proves unsuccessful, it is comparatively easy to discard it without disturbing too many people. Health districts in New York City have been found well adapted to this type of experiment and administrative research. Such services as the Consultation Chest Service for private physicians, the pneumothorax refill service, preschool conferences, record forms, and health education methods have all been tried first in a health district and then adopted as a policy for the rest of the city.

Need for Trained Personnel—One of the outstanding needs in district work is trained personnel. The district program will succeed or fail largely in proportion to the personality and capability of the district health officer and his staff. The program in New York City calls for the administration of health activities in each district by a full-time district health officer, whose responsibility it will be to know intimately the needs, resources, and opportunities of his district, to adapt the official program to meet those needs, and to give leadership to a coördinated program for community health in which

the interests of the department, the private practitioners of medicine and dentistry, and all health and welfare agencies will be welded. To fill such a position successfully, the health officer must have not only a sound medical background but, in addition, the viewpoint of a public health administrator. This requires experience and training in the broad field of public health. It is almost equally important that those associates of the health officer who are in charge of functional services within a district should have this public health and administrative viewpoint, rather than the strictly clinical interest which is more often found. Here and there among the professional group, one finds increasing numbers of individuals who have an interest in public health and executive work and who, as possibilities in the field open up, are eager to secure further training to fit them for this type of work. How to make public health training available for this group, and how to stimulate a better understanding of public health objectives among the professional groups in general, are questions of vital interest.

An important part of the New York City plan is the use of at least several of the health districts as training centers—for postgraduate study in public health; for the further training of the department staff in special services; and for the training in public health objectives and viewpoint of undergraduate medical students.

SUMMARY

Experience is pointing the way toward district health work as an administrative technic which will enable large cities to render their health services more effective by bringing them closer to the people. After study and experimentation along these lines since 1929, New York City officially launched its program of district health administration in 1934. Based on the experience of New York City, the issues which seem most important for the success of such a program are:

Long distance planning and the integration of the official program with all health and welfare activities in a district

Careful consideration and definition of the scope of the district services

A working out of relationships between the central organization and the districts, which shall preserve the necessary functions of formulation of policies and responsibility for the technical quality of special services by the bureaus, and place upon the health officer the responsibility of administering the departmental program in his district

The organization of a district for community interest and health planning

The importance of health education, and the adaptation of methods to suit an individual district

The use of districts to try out new administrative methods

The development of staff with public health viewpoint and training

Health Security*

THOMAS PARRAN, JR., M.D., F.A.P.H.A.
Commissioner, New York State Department of Health, Albany, N. Y.

IT is in the research laboratory that great events in medicine and public health usually are born. Just two weeks ago, however, there occurred in Washington one of the most significant events in the history of public health in this nation when President Roosevelt signed a bill appropriating money to launch the Social Security program.

Most people think of social security in terms of unemployment insurance and old age pensions, yet the law includes provisions through which, for the first time, we get a start on a national program to protect and promote the health of the people.

This is entirely appropriate, for the destitution arising from sickness or death of the wage earner is a prime factor among those circumstances which contribute to the insecurity of people. Yet much of this is preventable, as you have observed in your tuberculosis work where children become dependent and delinquent as the direct result of the death of a parent. Any national effort, therefore, to promote social security must include a serious attempt to prevent unnecessary disease and death.

The Social Security Act authorizes 10 million dollars to the U. S. Public Health Service, of which 2 million is for research to develop improved methods of disease control. Eight million will be allotted to the states for public health work, allotments being made on the basis of population, special health problems, and the financial needs of the states.

The Act also authorizes nearly 7 million dollars to the U. S. Children's Bureau for the health of mothers and children and for the care of crippled children. Grants from these funds are made on the basis of the number of live births in each state, the number of crippled children, the health needs and the financial status of the state, preference being given to the needs of rural areas. In general, it is contemplated that state and local appropriations will match the federal funds and that proper standards of service will be required for a cooperative attack upon those conditions which undermine the health of the people and contribute to insecurity.

Though it falls short of the millenium the good health officer longs for, this program reasonably may be expected to advance the health of this country to new and higher levels. Moreover, as in the past, a good and useful act frequently is useful far beyond its occasion. For example, when Sir Humphrey Davy in 1810 first discovered a greenish-yellow gas which he called chlorine, little did he dream that through its use today in sterilizing 85 per cent of the public water supplies in this country, typhoid fever would become a rare disease. Further, this same chlorine was used to cure wounds in the World War, and it bleached the

* Read before the New York Tuberculosis and Health Association, in New York, N. Y., February 25, 1936.

paper on which my remarks are typed.

Neither was the new order in public health, which has resulted from their charitable endeavors, foreseen by the founders of the State Charities Aid Association and the Charity Organization Society, through which the tuberculosis and public health movement of our state and city have come into being. These fine citizens saw misery about them. They sought to relieve it. As they inquired further into its causes, they were appalled to discover how vast and how vicious was the part played by tuberculosis. The term social security had not been coined; but in order to reduce the number of children made orphans and the number of families needing alms because of the illness or death of the wage earner, the group set out to fight tuberculosis. Then, as now, there was no specific either for prevention or cure of the disease; so education was used as a weapon against it. Through skillful political organization, the Legislature was induced to provide for the institutional care of patients. Indeed the "charity lobby" as it is known at Albany, led by Homer Folks, that devoted champion of the downtrodden and the sick, through more than 30 years, session by session, has built up a powerful body of supporters not only for tuberculosis work but for all good public health measures.

This citizen fight against tuberculosis, which you started, had a significance far beyond the 65 per cent reduction in deaths from tuberculosis, great as that accomplishment has been. Its greatest significance lay in the demonstration of a new weapon for use against *all* preventable disease—the fact that scientific knowledge of disease *could* be interpreted to the people; that public health action could be organized as a result of this education; and that an enlightened citizenship was of more value than quarantine laws in disease control. Before that time public health effort had been largely restrictive, legalistic, concerned primarily with the cleaning up of filth and the use of police powers by health officers. You made possible a new bi-partisan partnership of the people and their governmental agencies, state and local, which has been more valuable in reducing the incidence of tuberculosis than all the police powers of health officers ever on the statute books.

It seems clear, then, that from the efforts of just such groups as yours there has arisen in the American mind the desire not only to relieve misery due to sickness, death, and destitution, but also wherever and however possible, to ward it off entirely. This is not a transitory emotion born in the panic of economic disaster. Its roots go deep. As Sir Arthur Newsholme has said, "We all agree that no civilized community is justified in permitting any of its members to suffer, much less to die, for lack of food, clothing, shelter, or medical aid when sick. This obligation is everywhere acknowledged, both in America and Great Britain, however imperfectly it is met." What Sir Arthur elsewhere calls the "growth in the sentiment against suffering," expressed in your movement beginning a generation ago, was the first step in the modern method of meeting this obligation of a "civilized community." In the years since the beginning of your movement we have come into an economic life permanently altered from a self-sufficient rural and agrarian system into an interdependent urban, industrial system. In addition, education has become more general and medical science has advanced tremendously. The whole composite is a people not only in need of good public health service but a people who are increasingly aware that through good health there is available a large degree of that security which is their deep desire.

Since a population increasingly aware of its needs tends to require an increasing amount of health service at public expense, there are those who look upon this manifestation of representative government as an unreasonable burden upon the tax payer and an unwarranted interference with the right of the individual to be sick if he wishes. Chief Justice Hughes, who, as Governor of New York, sponsored actively the first tuberculosis control movement, has said:

> The settlement and consequent contraction of our landed domain, the pressure of a constantly increasing density of population, the interrelation of the activities of our people, and the complexity of our economic interests have inevitably led to *an increased use of the organization of society in order to protect the very bases of individual opportunity.*

Note that, " in order to protect the very bases of individual opportunity." According to the Chief Justice, then, and many of us feel that your work here in New York has been a first class demonstration of the theory, one must use social legislation in order to protect and advance individualism.

It matters little what party may be in power or what may be the current political slogan, the public when awakened to the saving of life and relief from suffering which is possible, will continue to provide for itself an increasing amount of tuberculosis and other health service as one means of security. Fortunately the cost is well within our ability to pay, as has been the cost of our campaigns against tuberculosis itself, against diphtheria, which your organization has sponsored since 1926, against typhoid, against yellow fever, against smallpox. In fact, it is far more economical of the public funds to prosecute such campaigns than to neglect them.

Do not hope for too much from the health measures which can be carried out under the present Social Security Act. They are only the first feeble steps of a people who at last are beginning to realize what they need. In public health work we stand today just about where we were in public education in the middle of the last century. I hope that in our attempt to provide good health for everyone we may avoid some of the blunders which characterized our effort to make an education available for all, through measures more generous than they were discriminating. If we do avoid such blunders, it will be largely the responsibility of people like yourselves who have been a generation ahead in your thinking about public health. You fathered the security movement originally, for you fostered the hope that for poor as well as rich, health and a healthful heritage were available, if good citizens would organize to provide them. New York has done well, though even here we barely have scratched the surface of what is possible in health protection. In many other states it seems apparent that not even the surface will be scratched without the stimulation, leadership, and help of a long-range, soundly planned national health program which it is possible to initiate under the Social Security law. I trust that you, as individuals and as an organization will guide, encourage, warn, and counsel the makers of that program, for it is built on the foundation stones you laid.

From my own point of view, it seems probable that effective health security can be achieved only through the extension of the New York method into the states where it does not now exist: which is a bi-partisan partnership of the people and the health agencies of government, state and local. In particular, I hope that you will make yourselves felt through such partnership in the prevention of three evils which may threaten the working out of social security. These evils, as I see them, are:

first, that because of our lack of vision and of experience and of health organization in many states, some funds may be spent for purposes of secondary importance; second, that in a few places, short-sighted authorities may look upon the relatively small federal grants of about 10 cents per capita as a means of relieving local budgets rather than as an opportunity of doing needed work; and third, that sometimes it may be forgotten that disease and death are non-partisan and that we may fail to place the right health official in the place because he is of the wrong political faith.

In my simple philosophy, the greatest need for health action is where the greatest saving of life and suffering can be made. I shall mention a few of the more obvious opportunities where experience has proved that the investment of public funds and citizen interest will bring a large return.

First, I would place the necessity for finishing the job in tuberculosis. The tremendous decline in the disease in this state from a death rate of 173 per 100,000 in 1905 to less than 50 in 1935, should not obscure the fact that it is still the leading cause of death in the age group between 20 and 40. Up to now we have talked and hoped for partial control. One of the most conservative of our public health authorities, Dr. Wade H. Frost of Johns Hopkins University, in a recent article advances convincing arguments that we can now begin to think about the eradication of tuberculosis. Only two factors, he says, bar this possibility. One is that in years to come the tuberculosis germ may become more virulent; the other is that we as a people may become less resistant to it. Neither contingency seems probable to him.

It is interesting to observe that a conservative scientific statement of today surpasses the most enthusiastic hopes of the last generation. Moreover, in working toward the goal of eradication, we know just where to focus our attack:

Upon first, the young woman in industry or the young mother,

Next, the worker in the dusty trades which form the background for many an unpublicized "Gauley Bridge" disaster,

Also, the Negro, the members of certain other racial groups,

And last, the man or woman who is ignorant, poorly fed and badly housed.

It is a great day for public health when we can anticipate the conquering of tuberculosis against which we have made progress. But an even greater opportunity exists for the eradication of syphilis against which we have made no progress, though its end results crowd our jails, our poorhouses, and our insane asylums. Yet there are specific methods of controlling it which are better authenticated by science than the means of controlling tuberculosis. Sweden and Denmark are two countries which have shown us how to do the job and we are well launched in a serious effort against syphilis in New York State and City.

Deaths from cancer are increasing and stand second among all causes. Yet at least 20 per cent of them could be prevented if cases could be recognized early, and if we had everywhere the facilities for proper diagnosis and treatment.

Deaths among children under 5 years of age have declined from 30 per cent to 8 per cent of the total since this organization was started, but the mortality rates of mothers in childbirth, and among babies in the first month of life, are still disgracefully high; although authorities agree that well placed effort, using proven methods, could within a few years reduce them to one-half the present level.

In addition, more children and adults alike suffer from faulty nutrition than from any other form of physical impairment except dental defects, which is one result of an improper diet. Yet

we do little but talk about correcting these conditions. It is high time we act; for our present knowledge of nutrition, as was forcefully stated at the last meeting of the American Medical Association by its president, Dr. J. W. McLester, shows definitely that the future of the race will depend upon the food we eat, to a greater degree than in the past we have profited by control of the communicable diseases.

Little is done in many of the states to restore crippled children to lives of usefulness, although New York and a few others have shown the way that much is possible. The Social Security plan to organize, assist, and raise standards of this work on a nation-wide basis is not only humanitarian but soundly economical.

In short, in each of the instances I have mentioned where the saving of life and the relief of suffering have been scientifically demonstrated to wait only upon organized effort, our national picture shows a great unevenness of performance which ranges from nothing at all to the good beginning—but not by any manner of means the full execution—of New York and some of her sister states. The first task, then, to be accomplished in a program for health security, would seem to be the leveling up of present services. The means of doing this are simple and include, first, the provision of the necessary human machinery. We need, and do not have, in every city and county, or comparable area, a well trained full-time health officer with a sufficient technical staff holding office on the basis of merit, not politics. The second need, is a minimum budget to perform essential tasks with national leadership, plus citizen backing, for the energetic prosecution of those tasks which will best repay, in human as well as financial returns, the expenditure of money and effort. But a leveling up to our present best standards alone will not achieve health security for us. The whole population, employed and unemployed alike, needs a better distribution of good medical and nursing care. For those who are destitute, all necessities of life including medical care must be provided. For the half of the population which even in the prosperous 20's had an income too small to provide for itself all necessary medical services, public funds must supplement individual effort.

There are several ways of doing this. It might be done through health insurance which would increase the availability of medical service and distribute the cost. Another proposal is State medicine which would make medical care available on the same basis as public education. A third possibility, the one toward which I myself incline, would require liberalizing of the present medical practice and coördinating it with public health and medical services. This would assist the private physician by providing for him laboratory, hospital, nursing, and other facilities for the treatment of his cases, and would relieve part of the load of catastrophic and chronic illness from the low income group. Whichever of these plans is adopted, or whatever modification of any of them, the fact remains that it must be possible for the whole population to secure medical care if we are to attain any semblance of health security.

Pneumonia, with its 12,000 deaths last year in New York State, is an example of a disease which can be fought successfully by coöperation between public health official and private physician. In the campaign now under way to reduce deaths from this cause, under the joint direction of the Medical Society of the State of New York, the State Department of Health, and the State Association of Public Health Laboratories, facilities for the best treatment of pneumonia are put into

the hands of every up-state physician; free laboratory tests are made to determine the type of pneumonia; and a new, better, concentrated serum, costing at retail from $20 to $100 per patient, is supplied without charge, by the State Department of Health to any physician who asks it. In addition, the State Department of Health, through its own staff of regular and W.P.A. nurses and in coöperation with the visiting nurse associations of up-state cities, volunteers to supply needed nursing service to all patients, not hospitalized. The State Medical Society volunteers to give its own members up-to-date postgraduate training in the management of pneumonia, under the direction of skilled pneumonia specialists. All agencies plan to work together for public education.

This is as yet a new venture. Its various factors are not yet in complete and perfect alignment. Nevertheless it is significant, both as an example of how public and professional agencies can work effectively together toward a public health end, and, concretely, how the private practice of medicine can be supplemented by better public facilities —in this case, laboratory, nursing, and serological service. It is too early to forecast definitely what the results will be, but conservative estimates indicate that a few years of continuous and concerted effort will cut down the deaths from pneumonia by at least one-fourth.

Nevertheless, when all these things have been done; after we have leveled up our present public health services and prevented much existing disease, and after we have provided good medical, nursing, and dental care for less easily preventable disease, we still need to control the unhealthful factors in the environment. Sanitary housing in England, and in many continental countries is considered a direct public health responsibility. Here we seem strangely oblivious to anything except its job-making possibilities. Food of the kind and quality for good nutrition is more important than clinics for the undernourished; yet we have made the most casual attempts to improve the diet of the millions fed at public expense and no more than a gesture at improving the food habits of the rest of the population. To provide these and other factors in a healthful environment requires a job at a fair wage. We should, by now, have learned that it is better judgment to provide useful work for the unemployed, than to continue, through insistence on the cheapest possible dole, to add continuously to the ranks of the physically and mentally unemployable. I emphasize the word "useful." Frequently we have failed to provide useful work because that requires planning, and there seems to be here and there the idea among partisans that it is somehow un-American to do planning for the public benefit. However, the continuing good health record of the people in this state which, during this past year surpassed all previous records, has resulted directly from our relief and unemployment methods—faulty as they are—no less than from the direct application of medical science to disease problems.

Though I have warned you not to hope for too much from the health program possible under the Social Security Act, I think that most of us are heartened by the fact that at long last this beginning is being made. Just as a generation ago the founders of your organization broke through the apathy of state and city toward tuberculosis, which caused so much needless suffering and destitution, so today we feel that we have cracked the crust of national indifference to public health as a function of government.

In behalf of your cause you have waged war in the state and city against the unscrupulous, the ignorant, and the self-seeking. I know, therefore, that

you will understand the necessity of caution in the working out of the national health program—the effort that will be required to avoid potential evils arising from lack of experience, lack of vision, and the tendency to partisanship. It is my hope that through this and through your national organization your influence may be felt for sound policy.

Whether you agree with me or not in the detail of health action which should be initiated, will you exert to the fullest your prerogatives as citizen-partners and consider ways and means of attaining, here and elsewhere, the three objectives with which I feel confident, and will agree in intent?

First, how may we level up our existing health services? And remember this means the wards and boroughs of New York City, cities and counties of New York State, as well as the backward and the progressive states. For in this way only shall we be able to lift the load of preventable disease.

Second, how may we re-distribute medical, dental, and nursing care? Half the population is unable to obtain sufficient care for themselves. Half the professional population has neither a living income nor a full-time task. Whether you like my way or another, some way must be found.

And third, how may we control the health factors in the environment—housing, food, work and working conditions, a living wage? For surely it seems an unscientific use of our effort and an unbusinesslike failure to order our affairs, when we struggle to control and to cure disease that could be prevented at the source.

These several considerations belong to the whole challenging field of health security in which, as you yourselves have demonstrated, citizen interest is equal if not superior to that of the health official. But in conclusion, let me remind you of our joint, special interest in health security, which requires an addition to your time-honored slogan. Let it now read: Tuberculosis is preventable; tuberculosis is curable; tuberculosis can be wiped out in our state and nation!

"In a plea for putting science and simplicity first, and dress suits and $5 dinners and keeping up with the Joneses last, one does not forget that formal papers and striking operations are not all that count at meetings. One close personal contact, one incidental idea from new research under way, one informal talk within the little group in one's own particular field—all these foci of scientific infection are often worth all the rest of the show put together. Friendships and relaxations—even golf—are grand parts of annual meetings."—Robert L. Dickinson, M.D., *J.A.M.A.*

Authoritative Standards and Association Policy*

W. H. FROST, M.D., F.A.P.H.A.

Professor of Epidemiology, Johns Hopkins University, Baltimore, Md.

THE immediate occasion for this discussion is some correspondence with several members of this Board concerning the Report on Educational Qualifications of Health Officers which was adopted last May by the Committee on Professional Education, distributed in September to members of the Governing Council and subsequently withdrawn. However, this report comes into the discussion only incidentally as a concrete example illustrating the two principal points which I wish to present for the consideration of this Board. These are: first, that the future policy and character of the Association are likely to be determined in large measure by the cumulative total of actions taken with respect to the establishment and maintenance of authoritative standards of procedure in certain fields of interest, as represented especially by professional education and administrative practice; second, that the questions of policy involved in these decisions receive very limited discussion in the Association at large.

The purpose of the Association is clearly defined in its Constitution. It is " to protect and promote public and personal health." The activities to this end, for which the Constitution specifically provides, are well summarized by Abel Wolman in his first report (1930) as Chairman of the Committee on Research and Standards.[1] In the introduction to this report, Mr. Wolman says:

> A member of an association of national scope may justly expect it to perform for him two major functions. It should provide for him an opportunity to exchange information with fellow workers, and should formulate standards of measurement in those fields where a uniform procedure would facilitate efficient action.

This statement, as worded, is not all-inclusive, but it indicates the line of cleavage along which the activities of this Association may be cleanly divided into two fields, both devoted to the same ultimate objective, the promotion of health, but quite distinct in immediate purpose and method.

On one side are activities, represented by the Section meetings and publications in the *Journal,* which are concerned with the constant introduction and discussion of new facts, new ideas and new procedures. The immediate purpose and effect of these activities is to keep up a continuous forward movement of knowledge, opinion and practice. For this forward movement the motive power is diversity of experience and opinion, freely expressed by individuals, speaking each for himself alone. Each new observation, opinion, or procedure thus presented gives an impulse to mass

* A statement presented at the meeting of the Executive Board of the American Public Health Association, New York, N. Y., December 19, 1935.

opinion, and the critical discussion which ensues tends automatically to correct error and to insure that the net movement will be in the right direction.

On the other side are those organized activities concerned with gathering up and formulating such agreement as has developed in the forum of free discussion. Whether the particular undertaking be the formulation of standards or the expression of agreement in some other form; this, as an organized activity, is characteristically the work of committees, speaking more or less explicitly in the name of the whole Association or one of its Sections.

These two activities of the Association, to foster diversity of opinion as the essential means to progress, and to formulate agreement as the basis for concerted action, are opposite in direction; and the main problem of Association policy is to keep them so balanced that neither will interfere with the other. To maintain this balance requires a just appraisal of the mutual relations and relative importance of the two functions.

The purpose of this Association is not merely to advance knowledge pertaining to health, but to apply it to the best effect; and to the extent that achievement of this purpose really requires explicit formulation of agreement, this function should be given precedence. But it is not often that *explicit formulation* of agreement and its expression as the authoritative opinion of the Association is really necessary—for effective agreement does not usually need to be stated in explicit terms. It develops naturally from discussion, in organized Section meetings, in the *Journal*, and in the informal contacts between individuals which lead to franker exchange of ideas and to mutual acquaintance, toleration, and respect. It is chiefly in this way that important principles and procedures for promotion of public health come to be generally accepted and applied, not at any given time, by everybody at once, but gradually, as the weight of evidence accumulates and makes itself felt by larger and larger numbers of those who are directly responsible for practical application. As compared with the sum total of *unformulated* agreement which is thus spontaneously developed out of free discussion, and year by year is translated into action, that which needs to be formulated in definite terms and expressed as authoritative opinion is relatively insignificant. Since it is, moreover, quite obvious that there can be no agreement of any value except such as is developed from adequate discussion, I believe it will not be questioned that to maintain a free interchange of information and opinion among its members is the first and most essential business of the Association. There is no danger whatsoever that this function will be over-developed or abused.

On the other hand, there is real and constant danger that the opposite function of formulating agreement and expressing it as authoritative opinion will be excessively developed. The essential danger inherent in authoritative pronouncements is that they purport to express substantially unanimous agreement based upon adequate evidence, and that they attempt to stabilize practice by throwing the influence of the Association against dissent. There are, within the field of public health, many principles of action, capable of simple expression, which are so firmly established that this Association can well afford to endorse them when any useful purpose is served thereby. But the urge for authoritative pronouncements does not stop within these limits; it extends to questions of a quite different character, scientific questions on which the evidence may be impressive but not conclusive, matters of procedure which

are not fundamental. With respect to such questions authoritative pronouncements purporting to express the opinion of a scientific body such as this Association are dangerous, even though they may be acceptable to a majority of the members, for if they fail to indicate the dissent as well as the agreement, they are misleading; and however much the intent may be disclaimed, the effect is, in some measure, to restrict the freedom of discussion which is the most essential function of the Association.

Perhaps the most frequent occasion for the expression of authoritative opinion by the Association as a whole or by one of its Sections, is in connection with the formulation and promulgation of standards. This is a recognized and useful function of technical scientific bodies; and Mr. Wolman, in the passage quoted, has properly included it among the important services which this Association ought to render to its members. He has, however, indicated the limits within which exercise of this function should be held, when he refers to "standards of *measurement* in those fields where a *uniform procedure* would facilitate *efficient* action." These are essential limiting conditions, that the measurement proposed should be valid, and that the uniformity established should be truly beneficial. Where these limits are accurately perceived and carefully regarded, standardization of procedure is appropriate and useful; where they are overlooked it becomes dangerous.

There are, of course, many activities within the field of interest of this Association, in which uniformity of procedure is a paramount consideration, and where valid measurement, at least in a relative sense, is entirely practicable. For the promotion of such activities, it becomes more or less imperative to adopt some uniform procedure. This may be said, for instance, of methods for determining and expressing the potency of biological products, for routine chemical and bacteriological examinations of water and sewage, for the classification of causes of death, and for presentation of basic tables of vital statistics. In some of these procedures the maintenance of uniformity may even be of such importance as to make it inadvisable to exchange an established method for one which is more exact or convenient.

There are, however, very many other procedures in which uniformity is not desirable, or a valid measurement not practicable. For instance, it is desirable and practicable to establish a standard measurement for potency of diphtheria antitoxin, but neither practicable nor desirable to establish a standard method of using it in the treatment of diphtheria; it is better to leave this to well developed individual judgment.

It is also necessary to consider whether standardization which may be justifiable for some other agency is appropriate to this body. For example, it is significant that this Association, which has concerned itself with establishing standard methods for the bacteriological examination of water, has not undertaken to establish standards for their interpretation with respect to safety; it has left this to an official body, the U. S. Public Health Service, which is responsible for the enforcement of regulations and under some necessity of establishing a more or less uniform basis therefor.

It is generally true that in proportion as procedures become more complex, requiring the consideration of many variables, some of which are not capable of exact measurement or quantitative expression, the principle of standardization becomes less and less applicable, and its promotion more and more in conflict with the broader purposes of this Association. Very many essential

procedures are of this character in the fields of professional education and administrative practice. That the promotion of standard practices in such fields is subject to legitimate objections and attended with real danger is generally recognized. It is attested, for instance, by the reports of two committees, both *advocating* the extension of standardization into new fields.

The Committee on Administrative Practice, in submitting the first *Appraisal Form for City Health Work,* says [2]:

> The committee has approved the official publication of an *Appraisal Form* only after long consideration and much discussion. Certain members of the committee seriously doubt the advisability at this time of setting up any formal standard of performance in health service. Certain others have felt that there is at present *no adequate scientific basis* for an attempt to formulate any numerical expression of the relative value of various health activities. A majority of the committee, however, have felt that the proven utility of the method more than outweighs its *inherent inaccuracies* and disadvantages, and have approved the schedule with the hope that in the next 3 years experience and study will permit the further perfection of the schedule and the *establishment of methods of evaluation* which will obviate the objections which have been offered to the present plan.

The Sub-committee on the Review of Standards, in its report (April, 1934) to the Committee on Research and Standards, advocating a comprehensive plan for the development of standards, says [3]:

> We are not unmindful of the *dangers inherent* in such a program as we propose. Standards may make for *rigidity* where there should be flexibility; standards *may make permanent that which should be transient.* We assume, however, that every procedure which may be developed to give impetus to the development of standards will be accompanied by a procedure for periodic review and revision. If this safeguard is established *pari passu* with each mechanism for the development of standards, we are confident that there need be *no greater danger* in a larger sphere of activity than has been evidenced in the smaller area which the Association has already cultivated.

The disadvantages which are specifically mentioned here—which the committee, in each instance, considers are outweighed by counterbalancing advantages—are those which are implied in Mr. Wolman's statement of limitations, namely, that the measurements proposed are inherently inaccurate, and that standardization may tend to establish a static uniformity instead of a forward-moving diversity of practice. The danger to the Association is that advocacy of a measurement which is not valid impairs its scientific prestige, and that any effort to stabilize practice comes into direct conflict with the Association's main function of moving opinion and practice constantly forward by the interchange of diverse opinion and experience.

These are grave dangers. If they are disregarded or too greatly discounted in the proposals which come up from year to year for establishment of more and more standard procedures, the inevitable result, over a period of years, must be to change the character of the Association from that of a scientific body, interested in promoting discovery and invention to that of an authoritative body standing in defense of its established special doctrine.

The extent to which a single decision in this field may influence the whole policy of the Association is illustrated by the Report on Educational Qualifications of Health Officers, presented by the Committee on Professional Education.* Assuming that the content of the report is well known, I will note only briefly its general import. It specifies in detail the content of an

* This report, after having been circulated to the members of the Governing Council and Fellows of the Health Officers Section, was withdrawn for further consideration by the committee. Hence, its specific recommendations are no longer before the Association; but, in one form or another, the general questions of policy which are raised in the report must eventually be decided by the Association.

8 month course of postgraduate instruction, and designates this

> . . . the minimum of special education, beyond that possessed by the average graduate of medicine which *must be had* by a young man entering public health administration in a *subordinate* position, *if he is to teach himself* successfully to carry on the work of a health officer.

It refers to "rigid enforcement" of these "minimum requirements"—by what authority is not specified. It implies that authority should be assumed and exercised to bring about adoption of the particular course which it has outlined by all institutions offering postgraduate courses for prospective health officers; and it raises, but leaves open the question whether universities shall be required to adopt a uniform schedule of hours to be allotted to the various subjects which are included.*

Leaving aside all detailed criticism, and confining attention to the report's broad significance, it is worth while to inquire what acceptance of these recommendations would imply with respect to the policy of the Association as a whole. It would place the Association in the position of advocating and defending not the general principle that health officers should be broadly and suitably educated, but the very different proposition that they should be *uniformly* educated, in accordance with a particular schedule *laid down by a committee of this Association.* The effect of this would be to project the Association into an entirely new set of external relations, placing it in an ill-defined position of assumed authority over the public officials who are responsible for the appointment of health officers and the universities which undertake their special education. These implications, involving a major change in the Association's external relations and policy, are definitely contained within the report. They follow inevitably from the primary assumption on which it is based, namely, that standardization of the educational qualifications of health officers is desirable and is a proper function of this Association. This is the really important recommendation which the committee, presents; in comparison with this, the rest is a matter of relatively unimportant detail. Yet the committee presents this particular recommendation as a matter of course, with no discussion of its validity and no intimation whatsoever that its acceptance by the Association would involve any significant change of basic policy.

It may be that the Association as a whole really wishes thus to alter its traditional policy. It may even be that to do so would be wise—though I cannot think so; but assuredly it is not wise to take action of such consequence without full public discussion, bringing to the attention of the whole Association the full implications as well as the intention of what is proposed.

This brings me to the principal point which I wish to present to the attention and consideration of this Board. It is that, under the existing organization and procedure of the Association, there is almost no informative *public* discussion of the *implications* of "standardization" in precisely those fields where its wisdom is most open to question, namely, in professional edu-

* The exact language of the report on this subject is:

"We do not believe it advisable at this time, if at all, to attempt to set up any definite schedule of hours of courses as a standard which must be adhered to by institutions offering such instruction. Much additional experience is necessary to determine what should be the proper allotment of time in such a course."

In the parallel report by the same committee on Educational Qualifications of Public Health Engineers, the corresponding statement confirms the implication that it is lack of sufficient experience which deters the committee from undertaking to specify the allotment of time. The statement here is:

"It is not advisable to attempt to set up any definite schedule of hours of courses since experience is necessary to determine the proper allotment of time to such courses. This should be left to the educational institutions for the present at least."

cation and administrative practice. In the reports of the committees dealing with these subjects, discussion of this underlying question is either omitted or is limited to the presentation of arguments on the positive side. In certain reports advocating standardization the existence of objections is mentioned, but they are dismissed as of no special consequence; and to the best of my knowledge, serious written discussion of the dangerous implications attending over-wide extension of standardization is not to be found in the public records of the Association of recent years.

In default of definite provision for general and public discussion of this question, as it arises in one form or another from year to year, the whole responsibility for determining the policy of the Association in this, its most precarious field of activity, devolves upon a series of committees—including as "committees" the Executive Board and the Governing Council. In none of these committees are circumstances favorable for really informative discussion which will eventually reach the general membership of the Association. The committee of original reference, whether it be one of the standing committees of the Association or a Section committee, begins its work under instructions which more or less definitely indicate that it is expected to produce a positive rather than a negative report —one recommending specific standards rather than advising against them; and within committees the impulse is naturally toward positive action. Discussion is, therefore, apt to begin with details of proposed standards rather than the underlying question of their justification; and, since it is not customary to present minority reports, any argument against the wisdom of standardization which is made within the committee is not likely to be presented in full to the Association at large or to the governing bodies. When specific proposals come to this Board, and later to the Governing Council, there is little opportunity for informative debate; and, quite properly, the general tendency of these bodies is to approve the reports of responsible committees unless there are strong and definite reasons to the contrary. Any extended discussion unfavorable to the principle must usually be presented as a protest against action which has already been taken by the Association; and while this condition is not prohibitive, it imposes a severe handicap upon the negative side of the debate.

I have no desire to bring into question here the wisdom of the actions already taken with respect to standardization—not because I am satisfied with them, but because this is not the time or the place to discuss them. Nor do I assume that all further extensions would be unwise. I have already indicated by belief that each proposal requires separate consideration. I do wish, however, to call attention to the fact—as I believe—that the whole machinery of the Association as it now stands is geared to promote the extension of standardization in fields where its wisdom is in question. That is, to say, the Association has established, in its standing committees, a strongly organized permanent machinery for moving the process of standardization forward, without provision for a correspondingly strong system of "checks and balances" to insure broad and critical discussion. It seems inevitable that unless stronger safeguards are provided, a more or less automatic extension of standardization in precarious fields will eventually change the whole character of the Association by placing it in the position of defending an ever increasing body of authoritative doctrine. For once the doctrine of uniformity has been extended beyond clearly defensible limits, there is no natural end-point at which it stops.

The only reliable safeguard, it seems to me, is some measure or combination of measures which will insure that each and every proposal for the establishment of questionable standards under the prestige of the Association be held in abeyance until it has been debated in the publications of the Association; this discussion to refer not to matters of detail, but to the underlying question whether the proposed standards really afford a valid and scientifically defensible measure of that which they purport to measure; whether the uniformity which they attempt to establish will really tend to promote efficient action; in brief, whether the Association can afford to defend them. As to how this may be brought about, I venture to offer the following suggestions, which are purposely stated in rather general terms, and limited to such as are believed to be practicable under the present Constitution.

1. It is suggested that committees generally, and especially those dealing with proposed standards, be instructed, or at least strongly urged, to record the dissent of individual members to statements and recommendations approved by a majority and, where this affords inadequate expression, to file minority reports. I do not know of any present rule of the Association which prohibits or discourages such record of dissent, but it appears not to be customary. Merely to establish the custom of expressing dissent where it exists within committees would, I believe, be the most constructive single step that is practicable. It would encourage and require more careful and exact statement on both sides, eliminating such ambiguous and conflicting statements as result from the attempt to give divergent views the aspect of unanimity, and it would present to the Association formulated questions for discussion rather than a single conclusion to be simply accepted or rejected.

2. For proposals which pass through the Committee on Research and Standards, it is suggested that this committee as a whole, or a sub-committee which takes no part in the initiation of any standards, review each proposal critically from the standpoint of Association policy, and where there seems to be any probability that legitimate questions may be raised concerning the justification of the proposed standardization, arrange to have the question presented for discussion in the *Journal*.

3. With respect to reports originating in committees of the whole Association, it is suggested that those which propose standard procedures to be promulgated in the name of the Association be required to stand before the Association merely as proposals under consideration for a sufficient period to allow ample time for the preparation of written discussions and their publication before they are presented for action by the governing bodies.

4. I would also commend, as a practice which might well be extended, the custom already inaugurated by the Committee on Professional Education of arranging a public discussion of its tentative proposals at each Annual Meeting of the Association. Such meetings might well be developed in such way as to bring out really careful and serious discussion of basic questions rather than details.

DISCUSSION

W. S. LEATHERS, M.D., F.A.P.H.A.*
Vanderbilt University of Medicine, Nashville, Tenn.

THIS memorandum refers to the provisional reports of the standing Committee on Professional Education. As *Chairman* of this committee, I wish to state that, in general, I am in accord with the principles and objectives set forth in Dr. Frost's discussion, and it is my impression that this also represents the attitude of the other members of the committee. Furthermore, I have no objection to the concluding recommendations which he presents. However, there are certain points of view in his discussion with which I am unable to agree.

There are statements and implication in Dr. Frost's discussion which are confusing and misleading, because they seem to me to be in conflict with the purpose of the Committee on Professional Education as prescribed by the Constitution and By-Laws of the Association. Article V, Section 5, of the By-Laws provides that

> . . . this committee shall be responsible for carrying out research and the development of standards for professional education and training in public health work and shall perform such other functions as may be delegated to the committee by the Governing Council with the view of maintaining professional qualifications of high standards.

I believe that overemphasis on differences of opinion in regard to the qualifications of public health personnel would result in a stagnation and lack of leadership which would be as unfortunate as the "standardization" of public health workers. The objective of discussions should be to reach agreements on fundamental principles on which to base constructive action. "Standardization" of public health personnel should most certainly be avoided, but minimum standards of educational qualifications are just as essential in public health work as they are in any profession or educational institution. General progress, in my opinion, will be encouraged by an agreement as to the minimum standards which are practicable at the present time, and by a judicious raising of such standards for the purpose of improving the quality of public health service. The American Public Health Association seems to be the organization which can contribute effectively to the accomplishment of this objective.

* This brief statement is made in response to a request of the Executive Secretary of the American Public Health Association. It concerns the memorandum presented by Dr. Wade H. Frost to the Executive Board of the American Public Health Association at its meeting on December 19, 1935.

Optimum Temperature of Incubation for Standard Methods of Milk Analysis As Influenced by the Medium*

M. W. YALE, PH.D., AND CARL S. PEDERSON, PH.D.

New York State Agricultural Experiment Station, Geneva, N. Y.

TWO years ago we presented a paper before this Association,[1] in which an incubation temperature of 32° C. for 48 hours instead of 37° C. was recommended for standard agar plates prepared from samples of milk and ice cream. This change was recommended because 32° incubation for 48 hours, (1) yielded higher colony counts than 37° C.; (2) reduced errors due to variations in incubation temperatures; and (3) resulted in a more constant percentage of the maximum count than 37° incubation. Thus, 32° incubation was a fairer and truer measure of quality than 37° incubation. Some of these advantages had previously been presented by others who felt that an incubation temperature near 30° C. should be used in official milk control work.[2, 3]

It has been known for many years that a number of types of media are superior to the present standard agar in regard to the ability to grow the bacteria which are found in milk. Recently, Hiscox, Hoy, Lomax and Mattick,[4] Anderson and Meanwell,[5] Safford and Stark,[6] and Bowers and Hucker,[7, 8] have published results which clearly show the need for changing the formula of the present standard agar.

As stated,[1] it is possible that a change in the composition of standard agar might so affect the counts that the temperature at which the maximum count would be obtained in 48 hours would be somewhat higher or lower than reported. The medium selected for study was tryptone-glucose-skim milk agar as described by Bowers and Hucker.[8]

While the separate ingredients were used early in the study, the medium was prepared for the most part by dissolving 21 gm. of Bacto-tryptone-glucose (Difco Laboratories, Detroit, Mich.) in 1,000 c.c. of distilled water by boiling to which 5 c.c. good quality skim milk, previously sterilized, were added and the complete medium sterilized for 20 minutes at 15 lb.

Standard peptone agar was prepared according to specifications outlined in *Standard Methods of Milk Analysis*.[9]

METHODS

The methods were for the most part the same as used in the previous studies.[1] The main difference was the inclusion of a 28° C. incubator so that curves could be more accurately constructed at this point. Usually 32–38 duplicate agar plates were prepared from a milk sample with each medium. From

* Approved by the Director of the New York Agricultural Experiment Station for Publication as Journal Paper No. 124, February 17, 1936. Read at a Joint Session of the Laboratory and Food and Nutrition Sections of the American Public Health Association, at the Sixty-fourth Annual Meeting in Milwaukee, Wis., October 10, 1935.

1 to 3 plates each were incubated at approximately each of the following temperatures, 18°, 21°, 45°, and 55° C., and 5 plates each at approximately 25°, 28°, 30°, 32°, 34°, 37°, and 39° C. The majority of the samples of pasteurized milk were plated on standard agar as well as on tryptone agar.

In each incubator the plates were grouped about a closed flask of water containing a thermometer from which 4 or 5 readings were made during the 48 hour incubation period ± 3 hours. The average temperature reading was assumed to be the approximate incubation temperature of the plates. The average number of colonies was determined for the plates in each incubator.

Average colony counts at each incubation temperature were calculated as percentages of the maximum average colony count. These percentages were plotted against temperatures, and a smooth curve drawn between points from which, by interpolation, the equivalent percentage for any temperature of incubation could be determined.

RESULTS

Thirty-three samples of bottled raw and pasteurized milk were collected from distributors in 16 cities and villages within 75 miles of Geneva. As examined, they represented the milk as it would have been delivered to the consumer.

Bottled Raw Milk—The tryptone agar curves for 11 samples of bottled raw milk collected (with one exception) in May and September, 1935, from 11 distributors in 6 cities and villages are shown in Figure I. One sample of so-called raw milk was apparently mislabelled. It developed a large number of thermophilic bacteria, the maximum count being 326,000 per c.c., which is unusual for raw milk.

FIGURE I—Relation between temperature of incubation and colony counts obtained from 11 samples of raw milk. Tryptone-glucose milk agar used. Incubated for 48 hours.

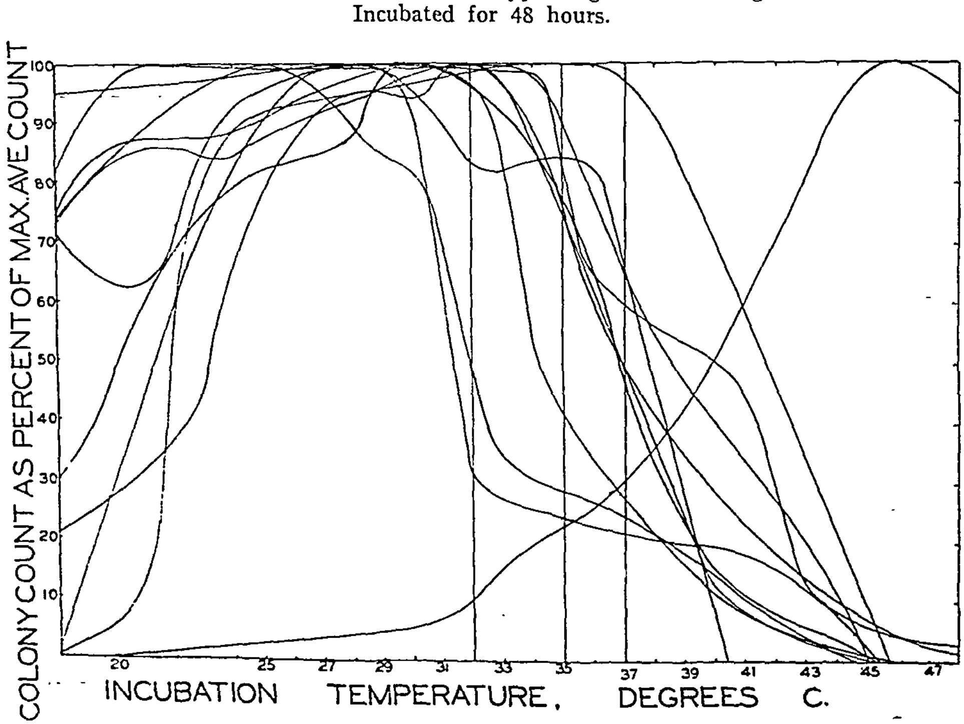

FIGURE II—Relation between temperature of incubation and colony counts obtained from 22 samples of pasteurized milk. Tryptone-glucose milk agar used. Incubated for 48 hours.

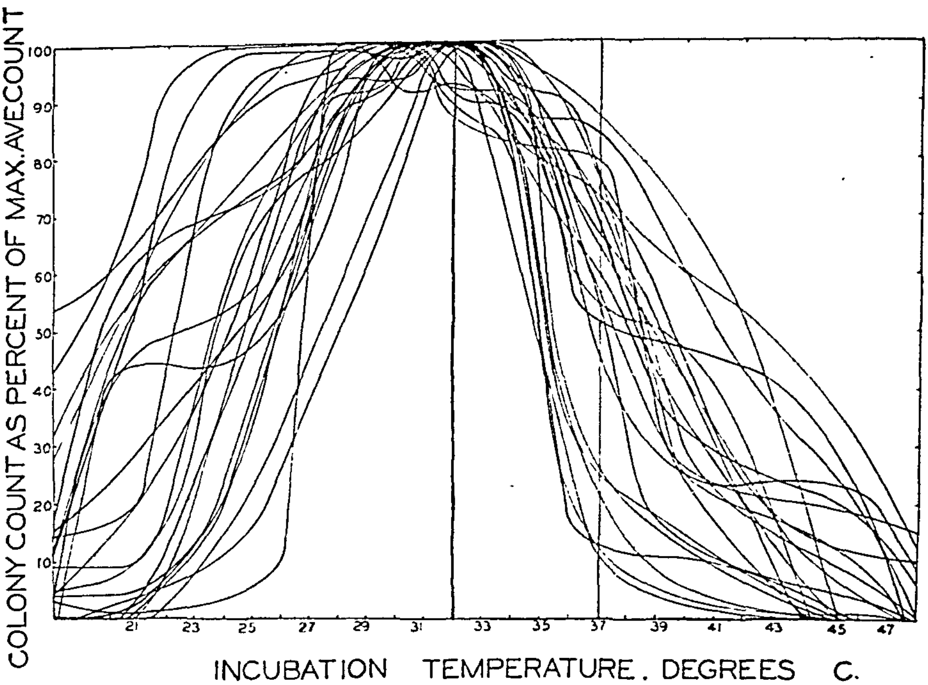

FIGURE III—Curves showing the average relation between temperature of incubation and colony count on tryptone-glucose milk agar and on standard peptone agar as obtained from Figures I and II of the present paper and from Figures I, IV, and V, Pederson and Yale, 1934.

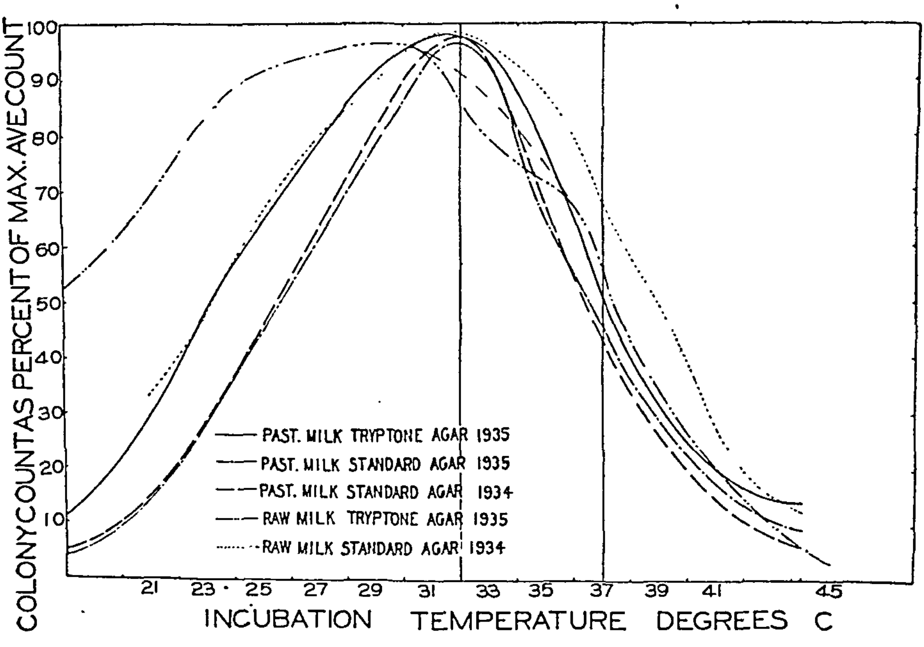

This, together with the fact that the dealer also handled pasteurized milk, indicates that it may have been pasteurized.

In the case of the 14 raw milk samples previously examined [1] by means of standard peptone agar, the maximum colony count on the average was obtained at 32° C., whereas with the 10 normal samples examined on tryptone agar in the present work, the maximum count was obtained at about 30° C. (Figure I). Individual curves for the 10 samples varied greatly.

Bottled Pasteurized Milk—The tryptone agar curves for 22 samples of bottled pasteurized milk collected between January and June, 1935, from 20 dealers in 13 cities and villages, are shown in Figure II. None of the samples showed the presence of thermophilic bacteria when agar plates were incubated at 55° C. These curves resemble those of standard peptone agar for 28 samples of pasteurized milk previously examined,[1] except in respect to the peaks which are considerably broader in the case of tryptone agar.

Whereas the great majority of the standard agar curves have their peaks at 32° C., over one-half of the tryptone agar curves have their peaks below 32° C. and, in 4 cases, below 30° C.

DISCUSSION

In the case of the samples of raw milk plated on tryptone agar, the average percentage of the maximum colony count was 95.5 per cent at 28°, 95.6 per cent at 30°, and only 85.1 per cent at 32° C. (Figure III). The low average at 32° C. was caused mainly by 2 samples which yielded less than 50 per cent of their maximum count at this temperature. The counts at temperatures below 32° C. are in the majority of cases nearer the maximum than found previously with standard peptone agar. Hereafter, previous work is referred to as 1934, the date of publication, while the present work is referred to as 1935.

A comparison of the average tryptone agar curve for the 1935 raw milk samples with the average standard peptone agar curve for the 1934 raw milk samples (Figure III) shows that the use of tryptone agar results in a broader curve and lowers the temperature of maximum colony development from 32° to slightly below 32° C.

At 37° C., standard peptone agar yielded on the average 68 per cent of the maximum count, whereas tryptone agar yielded on the average only slightly above 50 per cent of the maximum. While these percentages are not directly comparable because they are based on different samples, they suggest that 37° C. incubation may yield relatively lower percentages of the maximum count in the case of tryptone than in the case of standard agar. This is due to a relatively greater increase in growth of colonies on the tryptone medium at the lower temperatures.

In the case of the 1935 samples of pasteurized milk, the average percentage of the maximum colony count for tryptone agar was 96.0 per cent at 30°, 97.7 per cent at 31°, 97.2 per cent at 32° C., 94.7 per cent at 33°, and 87.7 per cent at 34° C. Based on 32° incubation, temperatures of 30°, 31°, 33°, and 34°, would on the average have caused errors of −1.2, +0.5, −2.5, and −9.5 per cent respectively. It is thus evident that variations of 1 and 2 degrees below 32° cause less errors than similar variations above 32° C.

Sixteen out of a total of 22 of the 1935 samples of pasteurized milk were plated on standard peptone agar as well as tryptone agar. Comparison of the average standard peptone agar curves for 1934 and 1935 show that they nearly coincide, which is significant because the 1934 and 1935 samples represented different distributors in

most cases. It indicates that a large number of samples would yield similar curves.

The average tryptone agar curve for the 1935 samples of pasteurized milk is broader and has a higher peak than the average standard peptone agar curve. The peak is at a temperature of approximately 31.3° C. as compared to 31.7° for standard agar. The fact that the curve is broader indicates that temperature variations from the point of maximum colony development will cause less errors in tryptone agar plates than in standard agar plates.

In the case of all of the average curves, the 37° C. count is in practically the steepest part of the descending curve, which is significant in showing that temperature variations from this standard cause maximum errors both in raw and pasteurized milk regardless of whether they are plated on standard peptone agar or tryptone agar.

Obviously, it is not practical to have different standards of incubation temperatures according to whether samples are raw or pasteurized; therefore, it would appear that a temperature slightly lower than 32° C. is best suited for 48 hour incubation of tryptone agar plates prepared from milk samples in general.

In the 16 samples of pasteurized milk which were studied, the maximum count on tryptone agar was on the average 44 per cent higher than on standard peptone agar. In 2 instances, maximum counts on tryptone agar were slightly lower than on standard peptone agar, 7.5 and 12.2 per cent, while in the remaining 14 they were from 2.7 to 151.6 per cent higher.

In the case of 6 of the 16 samples of pasteurized milk, plates were held an additional 48 hours to determine further colony development. With standard agar, the maximum 4 day counts were on the average 32.8 per cent higher than the maximum 2 day counts, while with tryptone agar, the maximum 4 day counts were on the average only 17.3 per cent higher than the 2 day counts. The percentage increases in the 4 day counts ranged from 7.4 to 56.1 in standard agar, and from 2.1 to 37.4 per cent in tryptone agar, thus indicating that not only more colonies developed during the first 48 hours on tryptone agar but that they developed more rapidly than upon standard agar.

The latter offers an explanation as to why maximum colony counts were obtained at somewhat lower temperatures on tryptone than on standard agar plates.

SUMMARY

On tryptone-glucose-skim milk agar, plates poured from raw milk developed the maximum number of colonies in 48 hours at temperatures slightly below 30° C. Plates poured from pasteurized milk showed maximum colony development at temperatures slightly above 31° C.

An incubation temperature of 37° C. for 48 hours is fully as undesirable with tryptone agar as with the present standard peptone agar because, (1) it yields only about 50 per cent on the average of the maximum 2 day count; (2) it is in the steepest part of the descending curve, and therefore errors due to variations in incubation temperatures are greater than at 30–32° C.; and (3) the percentage of the maximum 48 hour count varies greatly between different samples. On the other hand, an incubation temperature of 32° C. or slightly lower is fully as desirable with tryptone agar as with the present standard agar because, (1) it yields at least 95 per cent on the average of the maximum 2 day count; (2) it is at the top of the curve where the least errors are caused by temperature variations; and (3) the percentage of the maximum 48 hour count does not vary greatly between samples.

The results obtained with tryptone agar can probably be applied to other media which yield similar increases in colony counts over those obtained on the present standard agar.

Indian Service Hospitals

IMPROVEMENT and expansion of hospital facilities as part of the program to secure 1,000 additional beds throughout the country for the Indians is being advanced through awards made for hospital construction, financed by PWA.

An ultimate expenditure of approximately $4,250,000 is to include costs of hospital plant, equipment, quarters for personnel, and in many cases the development of utility services. The projects are designed for the Blackfeet and Crow Reservations, Montana; the Sisseton, Yankton, and Crow Creek Reservations, South Dakota; the Cherokee Reservations, North Carolina; and the Chippewa Indians in the State of Minnesota, concentrated at Cass Lake, Minn. In addition, the Indian Service is constructing, by work not built under contract, hospitals for the Zuni Indians of New Mexico, the Warm Springs group in Oregon, and the Western Shoshone reservation in Nevada. Another institution, at Yuma, Ariz., is under construction by contract. The Indian unit of 117 bed capacity at the State Sanatorium, Ah-Gwah-Ching, in Minnesota, and the Indian Service hospital of 38 bed capacity on the Colville Reservation, in Washington, have been completed and are now in use.

All structures are built for permanence, are modern in every respect, and where possible will be constructed of native materials. Stone has been gathered for the Blackfeet project; the Yuma hospital is being built of cement tile manufactured on the site by Indian labor; Indians of the Cherokee Reservation have completed quarrying stone for their hospital, and on the Zuni Reservation all rock was quarried by Zuni Indians. These projects, in addition to providing better hospital facilities, have been and will be the means of furnishing work opportunities in many Indians and white persons.—Department of the Interior *Memorandum*, Mar. 16, 1936.

Further Studies of the Composition of Media for the Bacteriological Analysis of Milk*

C. S. BOWERS AND G. J. HUCKER, PH.D., F.A.P.H.A.

Senior Microbiologist, Bureau of Laboratories, State Department of Health, Hartford, Conn., and Chief in Research, New York State Agricultural Experiment Station, Geneva, N. Y.

ACCURATE methods are essential in the determination of the number of bacteria found in milk. The composition of the medium used and the temperature of incubation are two of the most important factors which affect this accuracy. Recently, additional thought has been given to the composition of the medium used in *Standard Methods of Milk Analysis,* and an effort has been made to collect further data on the effect upon the number of colonies produced on the plates by changing the temperature of incubation. The data here presented are given to substantiate further our earlier work [1] which suggests that an agar containing tryptone, glucose, and skim milk should be substituted for the peptone-beef extract agar now accepted as the standard for milk work.

The historical development of the composition of standard agar has been outlined [1] in connection with studies which showed that the addition of yeast extract as well as certain other modifications of the present standard agar did not sufficiently affect the number of colonies produced to warrant their substitution for the present standard agar. However, it was found that a medium consisting of tryptone, glucose, and skim milk increased the count above that on standard agar by 33 per cent when raw milk samples were studied, and 147 per cent when pasteurized milk was used.

In the following comparative study the methods used were essentially those given in the *Standard Methods of Milk Analysis* of the American Public Health Association, with the exception that the media under study were substituted when necessary for the standard agar. Incubation was at 37° C. for 2 days.

Percentage Increase in the Number of Colonies on Standard Agar Caused by the Addition of Skim Milk and Glucose—Recent work by Stark and Safford [2] has shown that the addition of skim milk to standard agar increased the colony count. This investigation confirms earlier work by Hiscox, Hoy, Lomax, and Mattick [3] and others.

A study of 144 raw and 173 pasteurized milk samples confirms in general the results of these investigators. It has been found that the addition of skim milk to standard media will increase the colony count by 17 per cent, while the addition of glucose to standard agar produced a 35 per cent increase.

* Approved by the Director of the New York State Agricultural Experiment Station for Publication as Journal Paper No. 125. Read before the Laboratory Section of the American Public Health Association at the Sixty-fourth Annual Meeting in Milwaukee, Wis., October 10, 1935.

With pasteurized milk a similar (Table I) increase was found. From these results it is obvious that the addition

TABLE I

EFFECT OF THE ADDITION OF SKIM MILK AND GLUCOSE ON THE NUMBER OF COLONIES PRODUCED ON STANDARD AGAR

Number of Samples	*Percentage Increase in Number of Colonies on Standard Agar by the Addition of* Skim Milk	Glucose	Skim Milk + Glucose
144, Raw	17	35	..
173, Pasteurized	25	31	48

of either skim milk or glucose to standard agar will materially increase its efficiency.

Relative Numbers of Colonies Developing on Standard and on Tryptone-Glucose Agar—Since the report [1] on the relative efficiency of standard and tryptone-glucose-skim milk agar, 204 raw and 240 pasteurized milk samples have been studied (Table II). It was found that tryptone-glucose agar increased the colony count in raw milk by approximately 34 per cent; and in pasteurized milk by 47 per cent. These findings confirm, in general, the conclusions that a tryptone-glucose medium is much more efficient than the standard agar.

TABLE II

RELATIVE NUMBER OF COLONIES PRODUCED ON STANDARD, TRYPTONE-GLUCOSE AND TRYPTONE-GLUCOSE-SKIM MILK AGAR

Number of Samples	*Relative Numbers of Colonies per c.c. Expressed in Percentages* Standard Agar	Tryptone-Glucose Agar	Tryptone-Glucose-Skim Milk Agar
204, Raw	100	134	135
240, Pasteurized	100	247	...

The Effect of the Addition of Skim Milk to Tryptone-Glucose Agar—Since tryptone-glucose agar was suggested as a standard medium for the bacteriological analysis of milk, some discussion has arisen regarding the use of skim milk in connection with this medium. Certain difficulties arise when skim milk is recommended to be added to a medium as a routine procedure. Fresh skim milk is not available in all laboratories, and when added to agar it has been found in some instances to cause the appearance of a fine precipitate. This is true especially if the medium is held for any time in a liquid condition just prior to use. On the other hand the skim milk has certain recognized advantages when added to media. It has been reported to increase the number of colonies and also to impart an opalescence to the medium which brings into more bold relief the smaller colonies thus facilitating the counting of the colonies. For this reason, it was thought important to determine whether the addition of skim milk to the tryptone-glucose agar sufficiently increased its efficiency to offset these disadvantages.

TABLE III

EFFECT OF SKIM MILK ON THE NUMBER OF COLONIES PRODUCED ON TRYPTONE-GLUCOSE AGAR

Number of Samples	*Relative Numbers of Colonies per c.c. Expressed in Percentage* Tryptone-Glucose Agar	Tryptone-Glucose-Skim Milk Agar
326, Raw	100	104
421, Pasteurized	100	108

A total of 326 raw and 421 pasteurized milk samples have been studied to determine this matter. It was found (Table III) that in both pasteurized and raw milk the increase in the number of colonies on the medium which contained the skim milk over the plain tryptone-glucose agar was not sufficient to make a material difference in the end results obtained. On an average, in pasteurized milk, the addi-

tion of skim milk increased the counts by approximately 8 per cent; in raw milk an average of 4 per cent.

The Relative Efficiency of Neopeptone-Glucose Agar and Tryptone-Glucose Agar—There are several possible variations in the routine preparation of peptones under commercial conditions. During the production of tryptone it was found that by varying the process another type of nitrogen constituent for bacteriological media could be prepared which was given the name neopeptone. Neopeptone has been used extensively as a nitrogenous base for media to grow certain groups of organisms. Inasmuch as it appears to be a readily available source of nitrogen for certain types of bacteria it was thought advisable to study its efficiency in comparison with that of tryptone as a source of nitrogen in media for the bacteriological analyses of milk.

In all of the earlier studies in connection with the comparison of media, it has been found that the widest differences in colony counts occurred with pasteurized milk. For this reason, 420 samples of pasteurized milk were secured (Table IV) and plated both in

TABLE IV

RELATIVE NUMBER OF COLONIES PRODUCED ON NEOPEPTONE-GLUCOSE AGAR AND TRYPTONE-GLUCOSE AGAR

Number of Samples	*Relative Numbers of Colonies per c.c. Expressed in Percentages*	
	Neopeptone-Glucose Agar	*Tryptone-Glucose Agar*
420, Pasteurized	100	137

neopeptone-glucose agar and tryptone-glucose agar. It was found on an average that the tryptone-glucose agar produced a 37 per cent increase in colony count over that produced by neopeptone-glucose agar. In addition it was also noted that in 49 per cent tryptone-glucose agar gave the highest count, while in 45 per cent the highest count was found in neopeptone-glucose agar. In the remaining cases the counts were so nearly identical that no difference in the efficiency of the medium was recognizable.

From this comparative study it is obvious that tryptone is to be preferred to neopeptone as an available source of nitrogen for the organisms commonly encountered in pasteurized milk as reflected by the relative number of colonies developing on plates prepared with these two ingredients.

CONCLUSIONS

It is concluded that this further study confirms our earlier finding that tryptone-glucose agar is more satisfactory than standard agar for use in the bacteriological analyses of milk. The addition of skim milk to this medium increases the efficiency slightly.

It has been found that tryptone is approximately 37 per cent more efficient than neopeptone from the standpoint of number of colonies developing on plates made from pasteurized milk. Although the addition of skim milk and glucose to the present standard agar increases the colony count, such a modification does not result in standard agar becoming as efficient a plating medium as tryptone-glucose agar or tryptone-glucose skim milk agar.

DISCUSSION

MAC H. MCCRADY, F.A.P.H.A., AND JACQUES ARCHAMBAULT, C.E.
Division of Laboratories, Provincial Bureau of Health
Montreal, Québec

WE have used standard agar, standard agar plus skim milk, and tryptone-glucose-skim milk agar in a comparison of counts in our regular routine work. Results have been secured from 40 samples of raw milk and 45 samples of pasteurized milk. Our findings in regard to a comparison of these counts may be summarized as follows:

Frequency of excess, by certain percentage, of the different counts over the smallest count—

		Standard Agar	*Skim Milk Agar*	*Tryptone Agar*
Over 25% excess—	Raw	12	20	20
	Pasteurized	11	37	30
" 50% "	Raw	2	9	10
	Pasteurized	8	31	26
" 100% "	Raw	1	4	7
	Pasteurized	4	26	24
" 200% "	Raw	1	2	1
	Pasteurized	2	14	15

We have found that the plain and tryptone-skim milk agar plates are equally satisfactory from the standpoint of counting the colonies on the plate. The standard agar with skim milk produces a more turbid plate and is therefore less satisfactory to count. Particular attention is directed to increasing disparity between raw and pasteurized milk frequencies in excess over the smallest count as shown in the table.

Excesses of over 200 per cent are encountered in the standard agar with skim milk and in the tryptone-glucose-skim milk agar far more frequently among the samples of pasteurized milk than among the samples of raw milk.

Self-Preservation

PUBLIC health issues were put in homely terms by a judge in Tennessee who, according to the Commonwealth Fund *News Letter*, said that he would gladly pay what the health unit cost him as a taxpayer, just so that he might avoid having to sit up with his neighbors when they got typhoid fever.

Evaluation of Certain Media for the Detection of Colon Organisms in Milk*

C. N. STARK, PH.D., AND L. R. CURTIS, PH.D.
Laboratory of Bacteriology, Cornell University, Ithaca, N. Y.

AN ideal medium for the detection of colon organisms in milk should permit growth and gas production by small numbers of *Escherichia-aerobacter* organisms, and inhibit the growth of those lactose fermenting gas producing bacteria not belonging to this group. Aerobic and anaerobic spore-producing rods capable of fermenting lactose with the production of gas are well known (Creel, 1914; Winslow, 1916; Hall and Ellefson, 1918; Kahn, 1918; Norton and Barnes, 1928; Meyer, 1918; Ewing, 1919; Perry and Monfort, 1920; Hinman and Levine, 1922; Lisk, 1923; Norton and Weight, 1924; Schreiner, 1927; and Koser and Shinn, 1927).

Mixtures of bacteria, a lactose fermenting but non-gas-producing organism growing in the presence of non-lactose-fermenting bacterium but one which can produce acid and gas from glucose, may cause gas production in the absence of *Escherichia-aerobacter* organisms (Sears and Putnam, 1923; and Holman and Meekison, 1926). A satisfactory medium should inhibit the growth of one or both of these types of bacteria which may be responsible for false tests.

The toxic substances added to culture media to prevent the growth of false test organisms may also retard or inhibit growth and gas production by small numbers of *Escherichia-aerobacter* organisms (Stark and England, 1933). A satisfactory medium for the detection of colon organisms in milk should not be materially affected by changes in pH or by the additional protein material in the amounts of milk used as inoculum, which must be added to the medium (Stark and Curtis, 1935). The ideal medium may be approached but probably will not be attained.

The results obtained by us, in testing the ability of 6 media to inhibit the growth of bacteria often responsible for false tests, are shown in Tables I and II. Bacteria able to produce gas from glucose, such as the salmonella and proteus groups, are able to grow in all of these media. (Data to substantiate this statement are available but are not presented here.) The hydrolysis of lactose by the cocci, the growth of which is not inhibited in some of these media, would make possible gas production by cocci and members of the proteus group. The detoxifying effect of adding 1 c.c. of milk to all of these media, except formate ricinoleate broth, can be readily observed. These facts, we believe, show conclusively the unreliability of crystal violet, Dominick-Lauter, gentian violet, and brilliant green bile broths for use in the detection of *Escherichia-aerobacter* organisms in milk. The addition of 0.5 per cent sodium formate to brilliant green bile

---

broth easily doubles the total population of bacteria and the amount of gas produced by *Escherichia-aerobacter* organisms (data available, but not presented), and does not make this medium any less inhibitory to the growth of bacteria responsible for false tests.

Experiments conducted on formate ricinoleate broth, Stark and England, 1935, and Stark and Curtis, 1935, to ascertain its fitness as a medium for the detection of colon organisms in water and milk have shown 0.1 per cent sodium ricinoleate to retard slightly the growth of *Escherichia-aerobacter* organisms, but to permit abundant growth and gas production by one or more cells of this group. The growth accelerating action of 0.5 per cent sodium formate overshadows the growth retarding action of sodium ricinoleate, resulting in a larger population of bacteria than is produced in the lactose-peptone broth containing neither formate nor ricinoleate. The increase in the rate of growth and the larger total population of *Escherichia-aerobacter* organisms is believed to be due, in part, to the buffering action of sodium formate. The addition of formate to the medium is also the source of the increased amounts of gas. *Escherichia-aerobacter-salmonella* bacteria are able to produce CO_2 and H_2 from formic acid. This action results in the formation of NaOH and $NaHCO_3$ which prevents the pH of formate ricinoleate broth from going lower than pH 6.0. A medium containing lactose and maintaining a pH of 6.0 or higher is an excellent environment for growth and gas production by *Escherichia-aerobacter* organisms.

The fact that the salmonella group of bacteria is also able to produce gas from sodium formate is an advantage rather than a disadvantage, since the presence of these bacteria in milk should not be tolerated. Of the bacteria, tested by us, able to grow in formate ricinoleate broth, only the *Escherichia-aerobacter* and salmonella groups were able to produce gas from sodium formate.

Formate ricinoleate + milk	—	—	—	—	—	—	—	—	—

Results of duplicate tests repeated

It is believed that formate ricinoleate broth can be successfully used for the detection of colon organisms in milk because: (1) it inhibits the growth of false test organisms; (2) it permits growth and gas production by small numbers of *Escherichia-aerobacter* organisms; (3) it results in increased bacterial growth and gas production, by maintaining a favorable environment for growth; and (4) it is little affected by the additional protein material which must be added when inoculating media with 1 c.c. amounts of milk.

SUMMARY

The results of studies reported in this paper are believed to justify the following conclusions:

1. Crystal violet, Dominick-Lauter, and gentian violet broths are not satisfactory for use in the detection of colon organisms in milk.

2. Brilliant green bile broth has a better selective action which is partially destroyed by the protein material in 1 c.c. amounts of milk used as inoculum.

3. Brilliant green bile broth may be improved by the addition of 0.5 per cent sodium formate.

4. Formate ricinoleate broth is satisfactory for use in the detection of colon organisms in milk. It inhibits the growth of false test organisms and permits growth and gas production by one or more cells of *Escherichia-aerobacter* organisms. The nutritive value and buffering action of sodium formate results in increased growth and gas production. Tubes of this medium having 1 c.c. amounts of milk added, as must be done in testing milk, do not permit the growth of false test organisms.

The Prevention of Venereal Diseases in Sweden*

EINAR RIETZ, M.D.

Commissioner of Health, Stockholm, Sweden

AFTER a thorough investigation which was carried on over a very long period of time, a law was passed in Sweden by action of Parliament in 1918 concerning methods to be employed for the prevention of venereal diseases. The intent of this law was to employ the same methods for the prevention of venereal diseases as were used for other communicable diseases.

I shall now give a short account of the requirements of the law against venereal diseases and the procedures for enforcing it, and show curves demonstrating the variations in the frequency of venereal diseases.

The law contains the following principal points:

1. Every person suffering from venereal disease must submit to treatment by a physician and must follow his directions.
2. Every such person has the right, irrespective of the size of his income, to obtain free medical treatment and medicine, in case he is not being treated by a private physician. This includes free injections, free serologic examinations, as well as free certificates required by the public health authorities as to complete recovery or continued treatment. Hospitalization in a special general ward is also furnished free of charge.
3. Every physician treating a new case of venereal disease must try to obtain information about the source of infection.
4. Against patients, who do not properly follow up their treatment, and against individuals identified as the source of infection but unwilling to come to treatment, certain compulsory measures may be taken.
5. A person who knows that he or she suffers from venereal disease and who by carelessness causes its transmission, is subject to punishment of a severity up to forced labor.
6. Every marriage partner prior to obtaining a marriage license has to sign a statement certifying his or her freedom from venereal disease in a contagious stage.
7. The local public health authorities must publish information about the existence of the clinics for the treatment of venereal diseases.

The medical control of prostitution was simultaneously abolished. Opinions varied widely at one time among the physicians as to the expediency of abolishing this control but in the vagrancy law there is a good weapon available to the police for dealing with this class of women. The term vagrant as used in the legislation covers not only vagabonds in the strict sense of the word but also persons with fixed abode known to lead a harmful life. The punishment prescribed for vagrancy consists in confinement in a workhouse. Sentence of this is passed by the provincial governor after a preliminary warning.

The law defines venereal diseases as syphilis, gonorrhea, and venereal ulcer. Treatment is required during the infectious stage. By this is meant as long as infectious symptoms are present or as long as there is any possible danger of the infection being transmitted.

* Read before the Health Officers Section of the American Public Health Association at the Sixty-fourth Annual Meeting in Milwaukee, Wis., October 7, 1935.

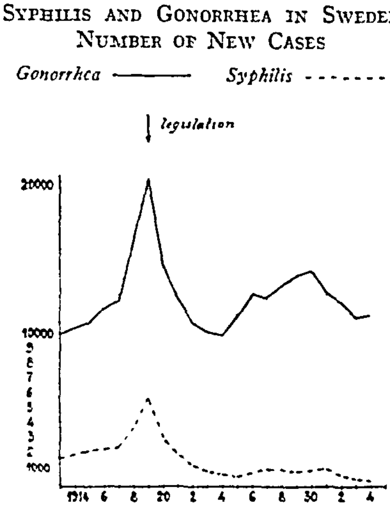

CHART I—Cases of venereal disease have been legally reportable since 1913, but in the beginning the reporting was probably not complete.

After a sharp increase during the war, the law was put into action and the decrease was promptly made apparent during the first years thereafter. During 1934, 11,500 new cases of gonorrhea and 431 new cases of syphilis were reported.

Gonorrhea has decreased to one-half its maximum. Syphilis has decreased to less than one-tenth what it was in 1919. There were in 1919, 3,000 new cases of venereal ulcer; in the last year only about 100. A great part of these were sailors, infected abroad.

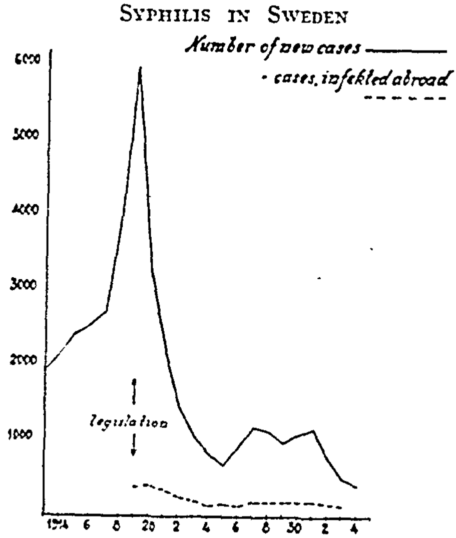

CHART II—This gives the figures for syphilis in Sweden: 6,000 new cases in 1919, 431 in 1934. During the last years about a fourth of the new cases were infected abroad. Of 431 new cases, 110 occurred in Stockholm, 212 in other cities containing a total population of 1,500,000 inhabitants, and 109 cases were in rural districts containing a population of 4,000,000 inhabitants.

This is applied in such a way that, for instance, a person infected with syphilis is entitled to free medical care for 3 years from the beginning of treatment. Pregnant women infected with syphilis at any time earlier likewise have the right to continue treatment to its completion.

Examination and treatment free of charge are furnished by the rural district physicians and by the health officers of the cities. In cities of more than 20,000 inhabitants there must be a special clinic with different receiving hours for men and women. If possible, women doctors are employed at the clinics for women. Special training is required of all these physicians.

The salaries of the physicians, the cost of medicine, and the serologic tests are paid for by the Swedish Government while the local communities themselves furnish the space for the clinics, the non-medical personnel required and the cost of hospital care. The physicians at the clinics have fixed salaries; the other physicians are to be reimbursed from the central government. If the work is on a large scale, fees are reduced along certain lines. The salaries of the physicians at the clinics are revised annually with regard to whether the work has increased or decreased.

A physician who has made the diagnosis of venereal disease in a person is required to inform the patient of the nature of his infection and the danger of transmitting it to others. He must also give the patient a pamphlet with printed directions as to what measures he must take in order to prevent spreading the disease. The

patient is also informed that it is forbidden by law to marry under these conditions or to subject any other person to infection. The stipulations regarding punishment are stated in the directions. The sick person is required to acknowledge in writing that he has received these directions. This point is especially important, as in this way the patient is made to understand that the State has control over his conduct and that carelessness cannot subsequently be excused on the plea of ignorance of the law. These written acknowledgments may be and have been used as evidence in court.

The physician is required to care for the sick person during the whole period of sickness or to report to the physician in charge of the health department if the patient has stopped treatment without furnishing proof that he is being treated by another physician.

It is the duty of the physician who first discovers venereal disease in a patient to try to trace the identity of the individual responsible for transmitting the infection.

The health officer in each city or province is the supervisor of this work. The report to the health officer of a new case contains the date of birth of the patient and the community of which he is a resident, but not his name. The report also contains the source of infection, if the patient has been able or willing to reveal the same, and in this case the name and address of the source is given. As a protection against blackmail the physician has to use his judgment as to the truthfulness of the patient's statement. In case the information is sufficiently detailed to locate the source of infection, a letter in a plain envelope is sent to this person. The number of the post office box is, however, stamped on the envelope so that the letter will be returned if the addressee is not located. This letter contains a printed order for said person to submit to examination and to deliver a certificate that either he is free from venereal disease, or is under treatment. The letter plainly states that the person may choose his or her own physician, but at the same time a list is enclosed stating which physicians or clinics will render free examinations and treatment. If the letter is returned or if no statement is received from the addressee within 4 days, a registered letter is sent. If this is returned or no statement received within 6 days the health officer makes out a notification to the police to bring the person for examination. The suspected source of infection is visited by the police or a police nurse and is then given one or two days to go to the clinic voluntarily, unaccompanied by the police.

The patient or "the new case," after the inquiries made at the first visit to the physician, is unmolested by the health authorities if he continues his treatment regularly. If he is irregular or discontinues treatment without a properly arranged transfer to another doctor, the treating physician has to reveal his name to the health officer and the procedure just described in connection with the search for the source of infection is applied. In this case the police order contains a notification that the person in question must be hospitalized. It is possible for him to avoid hospitalization if it is thought that the patient really will continue treatment regularly. However, if hospitalization is ordered, the patient must submit to hospital treatment until released by the health officer.

In Stockholm girls under 18 years of age are always hospitalized and not treated at the free clinics, in order to protect them from undesirable contact with older female patients in the clinics. In all matters pertaining to the investigation of patients and re-

porting of cases secrecy on the part of the doctors and nurses is required.

The wisdom of the venereal disease legislation at first was rather generally doubted by physicians, but in actual practice the difficulties have not been very great. The success of the law depends upon several factors. No single factor is more important than the coöperation of the doctors. Here it is a pleasure to report the loyalty of the profession. If cases exist which are not reported they seem to be cases of little importance in the spreading of the disease. No foci of social evil have ever been known to escape.

In retrospect one might admit that the doctors feared that the law would ruin their private practice. This of course did not prove to be the case. On the contrary the patients now are compelled to get complete treatment and they usually do their best to do so under complete protection against official interference. Patients who can pay the doctor, in general, are treated by private physicians in order to avoid the publicity of taking treatment at a clinic. The free clinics, at the same time that they erected a protection against excessively expensive private treatment, also created a number of salaried positions for specialists in venereal disease. The considerable decline in venereal disease which has resulted has of course influenced the income of the doctor, just as the disappearance of typhoid fever deprived the doctor of the former generation of the sum he used to set aside for his coal bill.

To most patients the shock of the diagnosis and being confronted with the responsibility which marks the procedure of the first visit to the doctor, suffice to make the patients follow the directions. Only against more or less

SYPHILIS IN STOCKHOLM
NUMBER OF NEW CASES IN 10,000

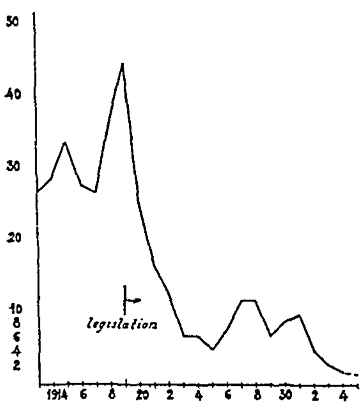

CHART III—This shows the number of new cases of syphilis in Stockholm per 10,000 population. In 1919 there were about 44 per 10,000 and now there is a rate which scarcely reaches 2 new cases in 10,000 people.

SYPHILIS IN STOCKHOLM, OSLO AND COPENHAGEN
NUMBER OF NEW CASES IN 10,000

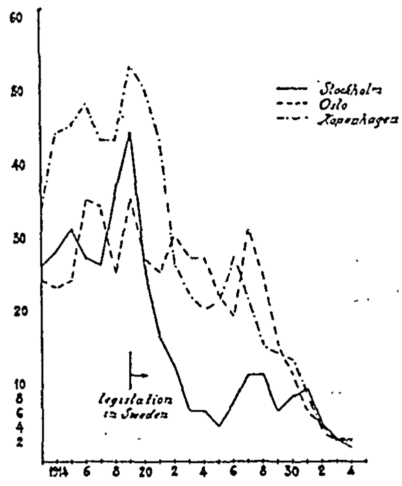

CHART IV—This gives a comparison of the prevalence of syphilis in the three capitals: Stockholm, Oslo, and Copenhagen.

In Norway and in Denmark there has been provision for free treatment for the poor for many years, and during the last years the health authorities in Oslo and Copenhagen have tried to search for the sources of infection in about the same way as we have done in Sweden.

Oslo and Copenhagen still have rates which are 50 per cent higher than those of Stockholm where the drop was earlier and more apparent.

anti-social individuals has it been necessary to enforce all the compulsory measures of the law.

The search for the sources of infection obviously is another cornerstone of the law. The mere existence of this clause has the effect of bringing a great many sources immediately under treatment without their even being reported as such. This is particularly the case with married people and with those in extra-marital relationships of a somewhat lasting nature. The actual figures for reported sources appear low, even when most patients know from whom they have got the infection. Rural districts and smaller towns may report figures as high as 50 per cent; in the larger cities the figures are much lower. In Stockholm a few years ago they were as low as 3 to 7 per cent, but as a result of intensive work by the health department sources are now reported in 15 per cent of the new cases. The personal equation of the physician of course plays a rôle and, if the figures of reported sources from a clinic show a tendency to drop, proper encouragements are instituted.

It is possible to locate the majority of the reported sources. Among those with whom contact has thus been established very few prove to be erroneously reported; others are able to prove themselves non-infectious—they have had time for treatment while the procedures of reporting and search have been going on. As many as 80 per cent of the reported sources have come under treatment in the city of Gotenbourg and as many as 50 per cent in Stockholm. For the whole country in the past year 1,072 sources of infection have come under treatment. This figure for sources is higher than during previous years.

In the clinics, where the less stable part of the patients are found, every effort, by such means as filing cards, is made to keep permanent track of the patients. The follow-up of irregular ones locates and brings back to treatment fully two-thirds, while one-third cannot be located. In this way 800 patients were brought back to treatment. This number probably includes many individuals in the infectious stage whose irresponsibility makes it doubly important that their treatment be complete.

Since the law was put in effect in 1919 there has been a considerable decrease in the number of persons suffering from the venereal diseases. This has been most pronounced in the rural districts and in the small towns, from which syphilis has practically disappeared. May I mention that Sweden has 6,000,000 and Stockholm 523,000 inhabitants.

Since 1917 Sweden has enjoyed very progressive legislation for the care of illegitimate children. This, in combination with the law against venereal diseases, has resulted in a marked decrease in the occurrence of congenital syphilis, which has dropped to about one-tenth of its previous figure. The organization of this care was started by the Swede, Velander, one of the pioneers in the modern treatment of syphilis. At present there exist in Sweden 3 nursing homes for children with hereditary syphilis, which each year have a greater number of vacant places. The babies are kept in these homes for 3 years and sometimes longer. A follow-up of 140 former patients who could be located, showed that 118 had no defect at all, either mental or physical, 4 to 25 years after discharge from the homes. Seventy-four had been kept under observation more than 10 years.

Though the law against venereal diseases has been in operation only since 1919, there is already a marked decrease in the occurrence of syphilis of the internal organs. A gumma of the liver is practically never seen;

syphilis of the heart and aorta is becoming a rarity; and the metasyphilitic diseases of the central nervous system are diminishing. Care has of course to be taken in the explanation of this development. The introduction of the Wassermann reaction and of arsphenamin a decade earlier than the legislation under discussion are factors in the history of syphilis, which here might count more than our law.

SUMMARY

Two points form the basis for the Swedish legislation against venereal diseases:

First—The search for and detection of the source of infection as in other contagious diseases.

Second—Though personal liberty is safeguarded in Sweden at least as carefully as in America, the law imposes a very definite restriction of freedom upon persons afflicted with venereal disease, compelling them to accept an amount of medical treatment, not according to their own choice, but according to the decision of responsible physicians. Upon individuals, under such control and to whom complete medical facilities for treatment are available at no cost, the nation further imposes the responsibility not to propagate the disease. For willful neglect of this responsibility, punishment up to the severity of forced labor can be imposed.

The results correspond to the ability of medical science of today in the treatment of these diseases: for syphilis the results are even better than could have been hoped for, but for gonorrhea decidedly poorer. It is believed that considerable further decrease in the frequency of gonorrhea might be obtained by better methods for treatment in order to get the patient non-infectious in a shorter time and by procedures of individual prophylaxis.

Thus we have successfully applied to the combating of the venereal diseases the experience and principles gained in epidemiology, medicine, and public health administration.

DISCUSSION

THOMAS PARRAN, JR., M.D.
State Commissioner of Health, Albany, N. Y.

DR. RIETZ has been very conservative in his presentation of this subject.

During recent years, reports have been coming out of the several Scandinavian countries, indicating a marked reduction in the prevalence of syphilis. In order to check the accuracy of these reports and to investigate the methods being used for the control of the venereal diseases in the Scandinavian countries, I visited Sweden, Denmark, and Norway this summer.

Without doubt, syphilis has become a rare disease in Sweden and in the other Scandinavian countries. We were convinced that notification of early cases of syphilis is relatively complete and accurate. The continued high recorded prevalence of gonorrhea, among other facts, supports this conclusion. Dr. Rietz has told you that only 431 cases of syphilis were recorded in Sweden last year. The population of Sweden is more than 6,000,000—approximately the same as upstate New York. Last year, there occurred in upstate New York more than 11,000 cases of syphilis. In similar measure, syphilis has become a rare disease also

in Denmark and Norway. In each of these countries, there are two basic principles underlying the control efforts: *first*, every infected person must take treatment; *second*, treatment without cost and of a good quality is made freely available.

The cold statistics are corroborated on every hand. Professors in the medical schools have difficulty in finding a sufficient number of early cases of syphilis to demonstrate to their pupils. In the Rigs Hospital in Copenhagen, the dean of the medical faculty and professor of obstetrics showed us his records—nearly 2,000 deliveries each year, of which 60 per cent are of unmarried mothers. During the past 3 years the number of cases of syphilis, as shown by routine Wassermann tests and careful histories, has varied from 30 to 35 per year, and the number of cases of congenital syphilis from 2 to 5. In the Wehlander homes for congenital syphilitics are many empty beds.

In Denmark and Sweden and also in Great Britain, the control of the venereal diseases is primarily a responsibility of the central government. No other health activity is the subject of such centralized responsibility. This indicates, I think, the importance which is attached to this problem.

During recent months, health officers in this country have been encouraged to hope that one or another method recently proposed for the prevention or cure of poliomyelitis would prove of value. Each of these methods has attracted national attention. The newspapers have described them in first page stories.

Splendid as it would be to have weapons with which to eradicate poliomyelitis, the effect upon the public health of this country would be infinitesimal as compared with the control of syphilis as has already been done in Sweden.

Dr. Rietz has brought us a gripping story of actual accomplishment. Syphilis in Sweden is no longer a major health problem. The methods by which this result has been accomplished can be applied to the United States. Dr. Rietz has described to us one of the most outstanding public health accomplishments of our generation; truly, it is a modern miracle in medicine.

In closing, may I paraphrase a statement of Dr. Stokes: How long shall we health officers in the United States concern ourselves only with the minor plagues while this major plague of syphilis continues unabated?

Patient of Louis Pasteur

According to newspaper accounts, Joseph Meister of Paris who, at the age of 9 was the first person whose life was saved by Louis Pasteur after bites from a rabid animal, arrived in this country in February at the invitation of the French Chamber of Commerce of the United States. M. Meister is now 60 years of age and his appearance in this country is inspired, according to the report, by a desire to revive interest in Louis Pasteur. Another reason, of course, is the French motion picture on the life of Pasteur which is running at the same time with an American film of the same story, both of which are highly commended by the critics.

Shellfish Report from the Standpoint of the Sanitary Engineer*

L. M. FISHER, C.E., Dr.P.H., F.A.P.H.A.
Sanitary Engineer, U. S. Public Health Service, Washington, D. C.

FOR the purpose of this discussion the term "shellfish report" is assumed to be the laboratory's report of the results of the bacteriological examination of shellfish when made according to the recommendations of a committee from this Association, adopted in 1922.[1] In fairness to the 1922 committee it should be remembered that the method of examination it recommended was intended to apply specifically to oysters only.

REASONS FOR THE SHELLFISH REPORT

The underlying reason for requesting a bacteriological examination of shellfish is a desire to know whether or not the use of the shellfish as a food may cause illness in the consumer. Unfortunately, it is not practicable for the laboratory to give a "yes" or "no" answer to this question. This fact at once makes the shellfish report, by itself, of less value than it might otherwise be. In addition to this the laboratory does not ordinarily examine the portion usually eaten, the "meat" or body of the shellfish, but examines the shellfish liquor.

It appears that the committee's reason for not recommending the examination of oyster meats, or bodies themselves, was that the additional labor and care involved in making examinations of oyster meats was, in their opinion, not justified by the additional information obtained.

The present method of examining shellfish can be said to be essentially a method for examining the liquid which has been in contact with the body of the shellfish, or the rinsings, so to speak. A portion of the contamination the oyster gathered from the water in which it was immersed is thus secured either more or less directly from oyster liquor or from the rinse water in which shucked oysters have been thoroughly agitated. The report thus made may be some measure of the oyster's activity in accumulating pollution from the surrounding water, but by itself is of course no reliable measure of its pathogenicity when consumed as food.

Another consideration which tends to lessen the value of the shellfish report when considered by itself is the fact that organisms of the coli-aerogenes group which are sometimes found in shellfish secured from clean areas are evidently not all of fecal origin.

These are some of the shortcomings of the present method of shellfish examination.

Some of the more useful phases of the shellfish report are as follows:

Taken by itself the shellfish report on shucked shellfish can be useful in checking the cleanliness of shucking-house operations and will tend to show

* Read at a Joint Session of the Laboratory, Food and Nutrition, and Public Health Engineering Sections of the American Public Health Association at the Sixty-fourth Annual Meeting in Milwaukee, Wis., October 8, 1935.

at which stage of the shucking and packing operations contamination is entering the product. It is thus useful in bringing about improvements in the cleanliness of shucking-house operations.

When the report is made in inland cities, on shellfish that were clean when they were shipped from the sea coast and which arrived in the original unopened container, it is an indication of the care with which the shellfish were iced and protected from contamination in transit. Making use of the shellfish report in this manner affords practically the only first-hand information concerning the condition of the shellfish as they reach the market that the health officer in the inland city has.

It has, by itself, and modified so as to include the examination of shellfish meats, also been useful in measuring the efficiency of clam cleansing plants. Used in this connection it has again, however, not been 100 per cent satisfactory, because the report can give no conclusive information concerning the presence or absence of pathogens. This fact has made progress in shellfish cleansing slow.

In the field of shellfish sanitation as in the field of water supply it has been necessary to use the laboratory report of shellfish examinations in a trial and error way. Not being able to get a definite answer to the question "Will it make the consumer sick?" it became necessary to depend on experience in the use of water supplies to find out. In this way there developed a kind of empirical formula for determining water standards. From experience it was learned that water coming from clean watersheds was safe. This fact later was tied in with bacteriological standards for water quality. Judging by standards applied in domestic water [2] supplies it could be assumed that shellfish coming from beds the water over which was of drinking water purity would be safe for consumption. Actually experience has demonstrated that this is so. However, if the taking of shellfish is confined only to areas where the water meets the Treasury Department Drinking Water Standards, many valuable beds at present in use would be lost to the industry. There are, moreover, stronger economic forces at play in the shellfish field than in the field of water supply. Water falls from heaven and is free. Shellfish must be grown, gathered, and prepared for consumption. This costs money. Moreover, they are not universally distributed as is water. They grow only in certain favored places. If we close growing areas unnecessarily you can be sure we will hear from business men, state legislators, governors, and congressmen. It is not as easy to enforce strict standards here as it is in the field of drinking water supplies. The regulatory authorities have therefore been guided by past experience with shellfish and have set up more lenient standards than those applying to drinking water. There is no precise knowledge of the possible further latitude which might be allowed without actually causing disease. It must be borne in mind, however, that the shellfish industry would suffer a tremendous financial loss if too much latitude were allowed so that a serious typhoid fever outbreak would result. Still the margin of safety between safe shellfish grounds and unsafe ones from a public health engineering standpoint should not be broader than is actually necessary to protect the public health.

Another problem that arises in connection with shellfish growing in waters of questionable safety is as to whether these shellfish can be safely consumed after having been passed through a shellfish cleansing plant. With how much contamination in the raw shellfish could such cleansing plants safely deal? Will such cleansing plants operate equally well when treating all kinds of

shellfish? Must a different method of examination be evolved for each kind of shellfish? The only way answers can be found to such questions, with our present lack of precise knowledge, is by the trial and error method; with human shellfish consumers in the rôle of guinea pigs. A little progress has already been made in this way. In England it has been shown that there is less typhoid fever among consumers of mussels which have come from moderately contaminated areas, and that have been passed through shellfish cleansing plants, than prevailed among the consumers of uncleaned mussels from the same areas. Similar experience is accumulating in this country with respect to soft clams.

An efficient laboratory method for determining easily and quickly whether certain shellfish would or would not probably cause illness if consumed would justify the establishment of definite standards for approval or rejection based only on the laboratory examination of shellfish. Such a method of examining shellfish—if one could be developed—would be direct and would be many times more valuable than the present method of seeking for circumstantial evidence of pathogenicity. It would justify the making of the statement that "limits of pollution could be given for oysters and oyster waters in the form of carefully phrased recommendations," whereas no real justification for phrasing such a statement on the showing of the laboratory report alone now exists. Not enough is known now concerning the degree of pollution to be associated with pathogenicity to make such a statement. It would be desirable to exclude from market all shellfish showing the presence of any organisms of sewage origin. Such a standard would, however, close nearly all the most valuable shellfish grounds in our waters from which shellfish have been marketed safely for years. It should be remembered in this connection that almost invariably when shellfish responsible for the cause of disease have been traced to their source they were found to have been gathered, stored, or plumped in shallow water or floats and near the shore where there was a short and direct connection between fresh sewage and the shellfish. In the present state of our knowledge, however, it would not be advisable to narrow the margin between contaminated but safe shellfish and contaminated unsafe shellfish. What is needed is more knowledge, not a reapplication of our present knowledge.

The shellfish report should state its findings in the most intelligible manner. To say that a sample of oysters scores 23, for instance, means little to the average scientist unless he has been working in the field of shellfish sanitation recently. It is in effect expressing the results in a code unintelligible to scientists at large and without much meaning to most sanitary scientists. To the man in the street it means nothing. The English methods of expressing results in terms of so many organisms per oyster is more intelligible. Likewise, the practice of examining the meats which are eaten rather than the liquor which is thrown away is to be preferred. Making meat instead of liquor examinations results in showing a larger number of organisms per oyster. In 86 pairs of examinations in which the meats were shaken up with sterilized shot and the resulting emulsion examined after the liquor had been examined as prescribed by *Standard Methods,* during the so-called hibernation period for oysters, the average number of organisms per oyster was 13 for the liquor examinations and 760 for the meats. This shows that not all of the contamination present in oysters is disclosed when examined by our present standard method.

In view of the very limited amount of information we get from the shellfish report we have been obliged to rely chiefly on our knowledge of bacteriological quality of the overlying water, the nature and degree of pollution entering the shellfish grounds, and the past record of shellfish coming from such areas with reference to the spread of diseases. These three factors have determined almost entirely whether or not a given shellfish area should be closed or be permitted to remain open.

There is a tendency now to attempt to differentiate between the organisms of fecal and of non-fecal origin. Should such a differentiation be practicable and be quick and simple in its application, it would still probably not change our present trial and error methods of differentiating between safe and unsafe shellfish areas.

Recently a good deal of work has been done in the isolation of *B. typhosus* from sewage, sewage sludges, and shellfish, following Wilson and Blair's methods or modifications of their methods.[3–8]

If a long series of reliable negative results for the presence of *B. typhosus* should become available for shellfish from shellfish cleansing plants, and if the consumers of shellfish from such plants should continue to be free from typhoid fever organisms, it would tend to confirm our confidence in the operation of such plants. The existence of such a test might disclose weakness in operation without having to adopt the more brutal method of having to wait for the development of typhoid fever among shellfish consumers. Until a simple method for detecting pathogens in shellfish is found we will probably have to continue to depend upon our present trial and error methods to determine the safety of shellfish grounds.

Any improvement in method of bacteriological examination of shellfish which will give more precise results will be an advantage, but not a great deal will have been gained until either a short, reliable and simple method of isolating pathogens will have been found, or until we learn something more about the degree of contamination to be associated with pathogenicity. We must still continue to use our old trial and error method with its unknown percentage of efficiency, but with its very definite effectiveness.

The nature of the problem makes it impossible to expect the development of any method which will permit a sharp line to be drawn between safe and unsafe shellfish if based only on the laboratory examination of shellfish. Pollution from sewers may be carried further by tide, rainfall, and wind today than yesterday; more pathogens may be present in the sewage tomorrow than today because of the presence of an epidemic, or the shellfish consumers may be less able to combat small amounts of infective material tomorrow than they are now able to do because of lowered physical resistance. There will always have to be a zone—not a line—between good and bad shellfish areas. More precise laboratory methods may make it possible to narrow the zone we now think necessary. Conclusions must continue to be the result of seasoned judgment and experience and must be formed in the light of all the information sanitary science can furnish.

Any method that gives us information concerning the contamination present in shellfish meats rather than in shellfish liquors will, it is believed, be more valuable than the present methods depending on the examination of shellfish liquors.

Some factors which would be helpful in our present state of knowledge are information concerning the relation between numbers of *B. coli* and of *B. typhosus* in sewage, in sewage contaminated waters, and in sewage contaminated shellfish. These are not

simple problems to solve, but if solved would supplement our present methods of arriving at conclusions in a very helpful way.

Cincinnati Lays a Solid Foundation for Future Public Health

THE publication by the Public Health Federation of Cincinnati of a Study of Mortality in the city represents a significant step in building for the future. This volume of 200 pages, with 200 maps and charts, of course concerns Cincinnati most directly. But as a sample of good procedure for health councils, this publication deserves wider attention.

For years the usual citizen reaction in Cincinnati to all forward-looking public health plans was that things were in satisfactory shape, and a complacent smugness was substituted for a frank facing of facts.

This volume on the actual mortality experience of the city by census tracts 1929–1931, shows the local sore spots and points to special preventive efforts based on the observed facts. The report already has given scientific guidance to the selection of an area for a 6 million dollar slum clearance project and in many such unpredictable ways will be a help to Cincinnati in future years for community planning.

Part I, by William S. Groom, is a study of mortality in 13 American cities by race, sex, age and specific causes of death. Part II, by Floyd Allen, is a study of resident deaths in Cincinnati by census tracts and in detail.

A limited number of these reports are available at $1.00 from Bleecker Marquette, at 312 West 9th Street, Cincinnati, Ohio.

Federal Control of Spray Residues on Fruits and Vegetables*

WALTER S. FRISBIE, F.A.P.H.A.

Chief, Division of State Coöperation, Food and Drug Administration, U. S. Department of Agriculture, Washington, D. C.

THE spray residue situation has been a problem with the Department of Agriculture for the last 20 years. During 1915 and 1919 the department made a field survey of spraying practices, including analyses of the fruit ready for market. The result showed that where the spraying schedules recommended by the Bureau of Entomology were strictly followed the residues were present in amounts which, in the opinion of the department, in the light of information then available on the toxicity of lead and arsenic, would not be injurious to health.

In 1919 the Boston Health Department embargoed a shipment of western pears found to contain heavy residues of arsenic in the form of spray material, in some cases in amounts equivalent to half a medicinal dose on an individual pear. This served as a warning to regulatory officials that the insect horde was increasing, with a resulting increase in the use of insecticides. In a conference at Washington, called by the Bureau of Chemistry and attended by the fruit growers, it was recognized that steps must be taken by that industry to clean its products from excess residues before marketing.

The field force of the Bureau of Chemistry, which then enforced the Federal Food and Drugs Act, was directed to make a careful survey of the fruit producing areas, particularly those of the western states. This campaign was repeated for succeeding years, and instructions were issued to the shippers to remove visible spray residues from the fruit before shipment. Many shipments were detained by the federal agents and by coöperating state officials, and fruit found to bear excessive residues was to be cleaned before moving in interstate channels.

The department at that time was confident that where strict adherence to spray schedules was the rule, thorough wiping of the fruit before shipment would constitute a competent safeguard. To meet the ever increasing insect infestation, growers not only resorted to more intensive application of sprays but employed so-called binders, casein or oil, to make the spray more effective. Our analyses disclosed that ordinary wiping would not adequately remove the residue where binders had been used. We found that in many instances the removal of all visible residue was not tantamount to a thorough cleaning. The department then, in coöperation with state experiment stations, undertook to

* Read at a Joint Session of the Association of Dairy, Food, and Drug Officials and the Health Officers and Food and Nutrition Sections of the American Public Health Association, at the Sixty-fourth Annual Meeting in Milwaukee, Wis., October 9, 1935.

devise better methods of cleaning, and through the Bureau of Chemistry there was perfected an acid solution for washing the fruit, for which a public service patent was secured in 1926. The Bureau of Plant Industry, another bureau of the department, had developed suitable mechanical equipment for washing.

About this time, or in 1925, the British press reported illness due to the consumption of American apples, and Great Britain served notice that in view of the high residues found, American fruit would not be accepted unless it conformed to the limits for arsenic established by the British Royal Commission which investigated the Manchester beer poisoning cases at the beginning of the century. That limit, frequently known as the international tolerance, is 0.01 grain of arsenic trioxide (As_2O_3) per pound of solid food.

Through the coöperation of the industry with state and federal officials, an export certificate plan was devised for large producing states of the West. This plan, which is in effect today, involves the employment of field analysts whose qualifications are passed upon by competent state and federal chemists and whose salaries are paid by the industry. Every export shipment contains a certificate of analysis showing the fruit to comply with the established tolerance. The fruit is also graded by the Bureau of Agricultural Economics of the department. During the year 1934 the Northwest examined 68,555 samples of apples in 35 privately established laboratories. Incidentally, the number of seizures of this certificated fruit is practically negligible.

At this time (1925) the department, still through the Bureau of Chemistry, undertook aggressive regulatory action; in fact, seizures had already been made prior to Great Britain's action, which was given some publicity in the metropolitan press. One of these was a carload of western apples consigned to the Chicago market. The claimant elected to contest the issue in the federal court, and so it became necessary for the government to introduce testimony as to the harmfulness of the fruit involved. Medical experts testified for the government, among them Dr. A. J. Carlson of the University of Chicago, and Dr. J. C. Geiger who represented the Chicago Health Department. The testimony of the experts was unanimous in declaring that such fruit would be harmful to those who ate it and the government received a verdict in its favor. This was probably the most bitterly contested spray residue case which the government has had to prosecute, and it gave assurance to the officials of the department that their course was a wholly proper and not an arbitrary one as had so frequently been alleged by fruit growers and other opponents.

In spite of the verdict in the trial at Chicago and the fact that the department had been guided in its administrative course by the advice of public health officials, as well as by the data obtained by the British Royal Commission, the department undertook to seek further advice through a committee of experts in view of the progress which had been made in the study of the effect of small amounts of toxic substances. This board of experts, consisting of Dr. Reed Hunt of the Harvard Medical School as chairman, and of such men as Dr. Carl Alsberg of Stanford University, Dr. Carl Voegtlin of Public Health Service, the late Dr. A. S. Loevenhart of the University of Wisconsin, Dr. Frederick B. Flinn and Dr. Haven Emerson of Columbia University, met in Washington the early part of 1927. At the conclusion of its deliberations, the committee advised the department that it regarded lead as the more significant of the two elements in arsenate of lead, the insecticide commonly—almost universally—applied to combat the codling moth. The department, therefore, un-

dertook to compel an observance of a tolerance in terms of arsenic which would also insure a safe product so far as the lead factor was concerned, based on the premise that in the commercial arsenate of lead the ratio of lead to arsenic is approximately 2½ to 1. It later developed as a result of numerous analyses that not in all cases was this ratio maintained; cleansing processes were not equally effective in removing both lead and arsenic. A quick and accurate method for determining lead was needed.

The Food and Drug Administration, which in 1927 took over the enforcement of the Act originally assigned to the former Bureau of Chemistry, undertook a study of lead determination, since no rapid and reliable method was available. In 1933 a method both accurate and speedy was developed, making possible a lead determination in 30 minutes where formerly 3 days had been required.

In 1933 the department first announced a tolerance for lead in addition to one for arsenic, and the announcement for 1935 fixed the tolerances at 0.01 grain per pound for arsenic, at 0.018 grain per pound for lead, and at 0.01 grain per pound for fluorine.

The number of seizures and prosecutions which have resulted from enforcement of this provision of the Act is impressive and to a degree discouraging. For example, during the fiscal year ending July 1, 1935, there were 338 seizures of fruits and vegetables containing excessive spray residue, and of these 299 were apple shipments, showing the importance of this commodity from a regulatory standpoint compared to all other fruits and vegetables.

To explain further what is meant by a discouring outlook, we find that in 1933 there were 137 seizures of apples and only 34 in 1934. In the 1934 report of the Food and Drug Administration is this significant statement:

> Since interstate shipments alone are subject to regulation under the Federal Act, the public will never be entirely protected as long as poisonous sprays are applied until all state authorities exercise the same degree of effective surveillance that is now maintained in some states.

While the Food and Drug Administration gratefully acknowledges the effective coöperation and assistance received from state and city food control officials, nevertheless the statement quoted should be given serious consideration.

Throughout our campaign, we have not been entirely happy to note a reluctance on the part of some state officials to require the observance of a tolerance for the intrastate distribution and sale of sprayed fruits and vegetables. A number of apple producing states in the East as well as in the West have taken every precaution to safeguard the health of their citizens through an insistence upon compliance by the growers with the tolerance announced for interstate shipments. Such action has been of tremendous value to this administration in its control program. Our only regret is that not all of the states have adopted similar measures. We know that state budgets have suffered, but there has been evident no general disposition on the part of state officials to issue a warning to the industry or to declare a tolerance for intrastate commerce. In fact, in one or two instances we know that responsible officials have declared to the industry that cleaning would not be required for sale and distribution within the state. While it is distinctly contrary to the Food and Drug Administration and to the Department of Agriculture to criticise the administrative policy of officials of sovereign states, we feel it is entirely proper at least to make a simple statement of fact, particularly when the health and welfare of the public is at stake. Assuredly it does not seem unreasonable to assume that every health and food official, every guardian of the

public welfare, should exercise all power at his command to safeguard the health of the people.

We realize too that state chemists as well as our own analysts have been handicapped until recently by lack of a satisfactory, quick method for determining lead. Now that a dependable method is available taking only 30 minutes of the chemist's time, we hope that there will be increased activity along this line; in fact, it is already evident in some of the state reports. Incidentally, it may be pointed out that a sample which complies with the tolerance for lead will be well within the limit for arsenic, except of course in those unusual instances when such insecticides as calcium arsenate are used.

The Federal Food and Drugs Act contains no specific reference to lead, arsenic, or other toxic substances. It does, however, contain a provision with respect to adulteration and the language of one particular paragraph declares that food is adulterated if it contains any added deleterious substance which "may render it injurious to health." A Supreme Court decision pointed out that food may be consumed by the strong and the weak, by the healthy and the sick, and if there is any possibility of injury to health the product comes within the ban of the statute. The tolerances which the department has announced from time to time have not been arbitrarily fixed but have been issued only after long, careful study by those competent to judge. They have been established in the light of modern toxicological thought which now recognizes unlimited potentialities for harm in the ingestion of minute amounts of arsenic and lead. This phase of the problem, however, is for presentation by others who follow on this program.

The important point for us to consider is the magnitude of the problem which faces regulatory health and food officials. The crop of apples this year will exceed 75,000,000 bushels, much of which will move interstate by truck shipment, especially in the central producing area. The fact that vastly more shipments were seized in 1934 than the previous year shows that the industry as a whole has not yet recognized the seriousness of this problem and the importance of thoroughly cleaning fruit before marketing. The Food and Drug Administration for several years has been spending one-third of its entire appropriation, or nearly $500,000 for this project alone, obviously one of vital concern to public health.

Lest the impression prevail that our outlook is too pessimistic, it should be recorded here that developments already during the 1935 harvest are distinctly encouraging. For example, recently 2 states, 1 in the East and 1 in the Midwest, have perfected plans, in coöperation with the Food and Drug Administration, for state control and certification of outgoing shipments. Expenses are to be defrayed in part by the industry, and in return the growers are to receive preliminary orchard service to determine the extent of cleaning necessary, followed by the analysis of each lot intended for shipment. If the sample is found to be within the tolerance, a state certificate showing this fact will be issued. Coupled with this plan is the announcement by regulatory officials of both states of their intention to warn the industry that sales within the state will be required to meet the same tolerance as those intended for interstate commerce. Rigid execution of this plan will result not only in a minimum of federal seizures, or no seizures, but increased protection to the citizens of the respective states.

Another interesting development is the passage of the first state laws designed to control the spray residue situation—in Colorado and Michigan. The operation of these laws will be

watched with particular interest not only by other states, which may in turn adopt similar measures, but by the Food and Drug Administration in anticipation of increased effectiveness in eliminating toxic spray residues.

This paper has dealt with arsenate of lead as the insecticide and with apples as the important commodity. At present arsenate of lead enjoys extensive use and, according to our information, is regarded by entomologists as the most effective weapon against the codling moth. Apples are the chief problem because of the size of the crop and the almost universal need for spraying. The department has had occasion from time to time to take action against other fruits and vegetables for excessive spray residue—pears, cherries, currants, celery, cabbages, cauliflower. These last 3 vegetables have in turn represented individual problems, but at present through intelligent use of proper insecticides and adequate cleaning methods, seizures are few and far between, although a number of seizures of broccoli were made during the year.

Research is going forward within the department, and independently, with the hope of discovering a substitute for arsenate of lead which will be equally effective against insect pests and less poisonous to man. Ambitious salesmen have endeavored to convince fruit growers of the relative harmlessness of fluorine compounds, but apparently the entomologists are not in agreement that this is an entirely satisfactory substitute insecticide. Furthermore, the researches in Arizona and elsewhere have shown the peculiar effect of small amounts of this element in the mottling of tooth enamel. In view of its distinctly toxic properties the department has issued a tolerance equivalent to that for arsenic. Some experimental spraying has been done with compounds of selenium as well as with compounds of mercury. It is doubtful, however, in view of the extremely toxic character of the compounds of these elements whether any commercial development will arise along these lines; certainly, the Food and Drug Administration will continue to exercise due vigilance in excluding from the market products which have been treated with these dangerous chemicals.

SUMMARY

The spray residue situation has been a problem with the Department of Agriculture for 20 years and its various bureaus have used their resources for research, for education, and for correction through regulatory measures. They will continue to do so. As a result of its endeavors, the Food and Drug Administration feels warranted in saying that the fruit and vegetable crop which moves in interstate commerce is practically free from toxic residues. We shall not be entirely satisfied, however, until, with increased recognition and supervision on the part of state food and health officials, we can say with confidence that all of the fruit and vegetable crop which has been subjected to spraying is entirely safe for human consumption.

State Control of Spray Residues*

W. C. GEAGLEY

Chief Chemist, Michigan Department of Agriculture, Lansing, Mich.

WITHIN the past few years the control official has recognized the acquirement on the part of the consumer of a public health attitude which is significant. We have come to a realization of the acceptance on the part of the public that their health, welfare, and general interest, as well as their pocketbooks, are being adequately protected by those charged with this responsibility. Have we not, as control officials, been too complacent in accepting our program of enforcement which has increased in efficiency since the early years? I am thinking in this connection of the spray residue situation which prevails generally in producing sections of the country.

In approaching this problem originally, the attitude of those in a position to know its significance realized full well the seriousness of this question; that we were confronted with an unusual condition. Science had already furnished the weapons for controlling insect pests in the shape of poisons, coupled with a policy and practice on the part of the producer of applying such materials in an effective way; but the public generally had not been fully advised, or adequately informed of the potential dangers from the continued use of small quantities of poisonous materials.

The means resorted to, led particularly by the federal control officials, in working on an educational basis with just sufficient regulatory action to impress industry of the seriousness, appeared to be the only procedure that could be followed.

Unfortunately, the state control officials in the producing areas, split up in factions as they were, or influenced to a large extent in restricted areas by the attitude of entomologists, horticulture departments, and experiment stations, retarded the acceptance of a program. Control officers who, after all, must stand the brunt and criticisms of enforcing regulatory laws, in many instances did not appreciate the seriousness of the threat to public health, and for that reason were slow and reluctant to put into effect measures within their authority and jurisdiction that would tend to correct conditions.

The consuming public has been the last to be informed as to what this means, because of the well grounded fears of those in authority that they might become unduly alarmed, and industry suffer materially because of their refusal to accept questionable products freely.

Regardless of fears, as the past few years have taught us, I sometimes question whether we are justified in following continually this policy. The success of the enforcement of regulatory laws depends fundamentally and basically on public support and understanding. When public support is lacking,

* Read at a Joint Session of the Association of Dairy, Food, and Drug Officials and the Health Officers and Food and Nutrition Sections of the American Public Health Association, at the Sixty-fourth Annual Meeting in Milwaukee, Wis., October 9, 1935.

there is opposition; obstacles are placed in the way; moneys are not appropriated adequately and competent forces to cope with such conditions are not provided for in many places. As state officials, many of us are face to face with this situation in our localities, in attempting to control the intrastate movements of fruits and vegetables that contain dangerous substances in amounts beyond that which are considered normally safe. I am convinced that the conditions prevailing in the states, the absence of definite policies on the part of state control officials, have seriously hampered and retarded the progress for the control of interstate shipments.

It is pertinent to point out that a survey made in several states of programs in force for the control of spray residue will show a woeful lack of appreciation, as well as of definite action and policies along control lines.

We shall find, however, that a movement has been started, and will probably continue to grow and develop, in assisting industry to meet this problem by providing service features which enable the grower to determine conditions prevailing at the time of the harvest of fruit.

I believe we can appreciate what it means to industry to have such features available. On the other hand, it should be apparent that a definite regulatory enforcement program should be carried out in connection with the service features which have been inaugurated in some states.

Coupled with a definite program of enforcement should also run parallel a definite informative policy that would clearly point out to the consumers and to industry the seriousness and the purposes behind control measures, and in this way gain public support in any endeavor for corrections. The thought is that this practice would go a long way toward stimulating confidence in control officials and their action, which would enable them to accomplish more than they otherwise could do.

A program for controlling interstate shipments of fruits and vegetables containing excessive quantities of dangerous poisonous substances could well be developed along the following lines:

1. Information should be developed from all sources pertaining to the necessity for regulating this condition; the advantages in following such a plan; the protection that would accrue to those engaged in production; in the handling or merchandising, and in the consumption of such items; just how such a program would affect the producing industry and the distributors; and this information given the widest publicity on the basis of the fact that it is logical, sound, and in the interests of the community.

2. The support of the medical profession, public health officials, agricultural colleges, experiment stations, entomologists, and other organized groups who have the interests of industry and the public at heart.

3. A carefully planned enforcement program, so developed and worked out that it will be practical, inconvenience industry as little as possible, and at the same time be effective, and compulsory in that every shipper and all movements of fruits and vegetables likely to be contaminated will be subject to the same control features.

Such a program should then be given the widest publicity in order that the industry could prepare itself to comply with any and all reasonable demands made upon it.

4. To those control groups in producing areas where facilities are not available which would enable the producer to determine the condition of his fruits and vegetables at the time of harvest, service features could be provided for by establishing control stations, chemical laboratories, and technical services at a nominal cost to industry which would be purely of an informative character but carefully segregated from enforcement features.

A general plan such as outlined, if made uniform in adjoining states and correlated carefully with the interstate shipment of fruits and vegetables, would exact the same compliance from all parties concerned, and because of its obvious fairness there would be no criticism as between one group, or one

state, and another. Until such a program can be developed, I can see no permanent solution of this problem.

The State of Michigan, this problem being of an acute character, has endeavored to follow to some extent the above plan. There have been established service laboratories and inspection stations throughout the producing areas which provide for the examination of fruits and vegetables for the producers at a nominal cost, and when it has been determined by the producer that his fruit is in an acceptable condition for marketing, he may request an official collection of representative samples for analysis, and, upon finding that tolerances established have not been exceeded, the state will then furnish a certificate identifying that lot of fruit and indicating that representative sampling indicates that it is not in excess of the tolerance and is, therefore, acceptable on the market.

There are a number of other features that are being worked out in connection with the service program of the state which ultimately, we believe, will be of benefit to both the consumer and producer.

There is also being inaugurated a definite state control of intrastate movements with the object in view of preventing the inter-city movements of fruits and vegetables containing residues in excess of established tolerances.

A Move in the Right Direction

". . . Fortunately, General Reynolds, the new Surgeon General, has the breadth of vision to recognize the fact that the medical professions comprising the various Corps making up the Medical Department of the Army have their own professional standards and problems that are peculiar to each service and that they should be in charge of their own officers under the supervision of the Surgeon General, as Chief, who represents all the Corps comprising the Medical Department.

Accordingly, Surgeon General Reynolds issued an order, under date of November 29, 1935, discontinuing the Veterinary Service as a subdivision of the Professional Service Division. In the future the Veterinary Service will function as the Veterinary Division of the Surgeon General's Office."—*J. Am. Vet. Med. Assn.*, Feb., 1936, p. 113.

Pharmacology of Small Quantities of Lead and Arsenic*

DR. A. J. CARLSON

Professor of Physiology, University of Illinois, Chicago, Ill.

ANEMIA and pallor, lead line of the gums, painful intestinal colic, injuries to the nervous system, kidneys, and liver, and a train of other symptoms follow prolonged intake of minute amounts of lead or lead compounds. This makes it necessary to see to it that solutions or sprays containing lead do not leave enough of the lead upon the fruits or plants to cause chronic poisoning even in persons who may eat a great deal of unwashed fruit over months or years. This quantitative aspect must be further emphasized because of the great variability in tolerance to lead in man as seen in mass poisonings and in examinations of workers exposed to similar conditions in the lead industries, and because of the very limited increase in tolerance that one may expect in man.

One must also keep in mind that fruits are particularly the food of the sick and infirm who have had their factors of safety lowered by infections or organic disease, and that they are consumed by alcoholics and by persons who have had their strength sapped by poor hygiene and inadequate diets. Moreover, whatever lead one may absorb and store through eating lead sprayed fruits is added to the lead intake from other sources; that is, other foods, street dust, street and garage vapors (ethyl tetra lead), certain drinking waters, etc. In the tens of thousands of workers who come into closer contact with lead through the several hundred branches of industry in which lead is being used in one form or another, the addition of lead from sprayed fruits may be especially significant. The estimates of the minimum daily intake of lead necessary to produce distinct plumbism vary with the investigator and the time necessary to show the symptoms of poisoning. As examples, the estimate by Sollmann is a daily ingestion of 10 to 20 mg. to produce severe poisoning, and by Gaertner 4 to 7 mg. daily to do so within a few months. Others have placed the values as low as 1 mg. per day. Naturally, with higher doses the effects are much more prompt and severe.

Chronic arsenic poisoning resembles that of lead with its gastrointestinal catarrh, liver damage, impaired nutrition, and neuritis. In regard to the probability of chronic arsenic poisoning, contacts with arsenic in daily life are frequent owing to its use in cosmetics, Paris green, poisons for flies and vermin, etc. However, the usual artificial coloring of arsenic warns one against its dangers, and arsenic in wall-papers in general has been reduced

* Read at a Joint Session of the Association of Dairy, Food, and Drug Officials and the Health Officers and Food and Nutrition Sections of the American Public Health Association, at the Sixty-fourth Annual Meeting in Milwaukee, Wis., October 9, 1935.

to traces. Though arsenic is toxic in milligram doses and is widely distributed in water, coal-smoke, wine, salt, and so on, which give rise to traces in the human body, the usual intakes from such sources are not proved to be injurious. Although fruits after being sprayed, *e.g.*, with lead arsenate, retain this rather tenaciously, traces retained after ordinary washing would probably not be clearly harmful as to the arsenic, though the same general considerations hold as in case of lead. There is, however, this important difference—that a very considerable tolerance to arsenic may be built up, so that several times the quantity that would be severely toxic as an initial dose of arsenic may be taken later with apparent impunity.

The complete pharmacology of small quantities of lead, and of arsenic, taken for long periods has not yet been written. It is usually assumed that ingestion of lead below the amounts producing distinct lead poisoning is non-injurious. Future research is likely to prove this assumption invalid.

Camp Permits Required in Maryland

NEARLY a hundred tourist camps are operated in Maryland, according to a recent check-up of permits granted last year to owners or operators of camps and recreation grounds by the Maryland State Department of Health. The total number of camps which met the sanitary requirements, and which were duly posted after inspections by the county health officers, or the Bureau of Sanitary Engineering of the State Department of Health, was 167. Included in this total were 93 tourist camps, 49 recreation camps, 1 labor camp, 3 that were used for religious exercises, and 21 picnic grounds.

In preparation for the coming season, Dr. R. H. Riley, Director of the State Department of Health, has notified camp owners or operators of the sanitary requirements which must be met before the camps may be opened. No camp, whether new or old, may be operated without a permit; permits do not hold over from season to season. The state regulations apply to any premises used as a camp or picnic ground for a period of 6 days or longer, and accommodating 10 or more persons.

Spray Residues*

From the Viewpoint of the State Health Officer

WILLIAM F. COGSWELL, M.D., F.A.P.H.A., and JACOB W. FORBES
State Board of Health, Helena, Mont.

THE problem in Montana of spray residues has been largely concerned with those fruits or vegetables being shipped into the state rather than those grown within the state. Production of vegetables on a commercial scale is confined for the most part to a few truck farms near the more populous centers or to production for canning. The vegetables canned on a commercial scale in Montana are not such as to require use of poisonous sprays which leave residues in amounts capable of causing injury when used for human consumption.

In the summer and fall of 1932 Montana was hit with an epidemic of roadside fruit and vegetable stands. During a survey of the sanitary conditions around these establishments it was observed that a number of different kinds of apples and some pears were fairly well coated or were heavily spotted with some foreign material. Samples were collected and examined in the laboratory for suspected spray residues. All samples suspected of carrying excessive spray residue were found to exceed greatly the federal tolerance. These roadside stands were quite widely distributed but concentrated around the more populous communities. Because of the cumulative effect of arsenic and the menace it would become to any community where an appreciable amount of this fruit might be eaten, the State Board of Health believed some concerted action to control the situation was necessary, since the fruit had been brought into the state by truck.

A conference was held in Spokane with the Chief of the Seattle Station of the Federal Food and Drug Administration. As a result, a chemist and inspector from the Seattle Station were sent to Montana and worked with us for 3 weeks, sampling, analyzing, and instituting federal action against all interstate shipments found exceeding the federal tolerance for spray residue. After the federal men left, this work was continued in full force by the State Board of Health.

The Montana State Horticultural Department had already established stations, or so-called ports of entry, at various points near the Montana line on the principal highways to check fruit and other produce for insect infestation, grades, and labeling. Thanks to the very hearty coöperation of the Horticultural Department, we were able to establish an extensive sampling program of all trucks bringing produce into the state. In addition to these ports of entry the Horticultural Department also had, in all of the principal cities, inspectors whose duty it

* Read at a Joint Session of the Association of Dairy, Food, and Drug Officials and the Health Officers and Food and Nutrition Sections of the American Public Health Association, at the Sixty-fourth Annual Meeting in Milwaukee, Wis., October 9, 1935.

was to check all rail shipments of produce.

By the time this sampling program was established it was found that rail shipments of fruit were as badly adulterated as truck shipments. This resulted in the adoption by the State Board of Health of a regulation requiring all shipments of fruits or vegetables into Montana to be accompanied by a competent certificate certifying the product to be within the federal tolerance for spray residue.

Samples collected by the inspectors were forwarded to the State Food and Drug laboratory for analysis. All shipments found to exceed the tolerance were ordered held until washed or otherwise treated to bring them within the tolerance, or else were ordered destroyed. Samples of rail shipments, where interstate shipment could be established, were taken and submitted to the federal authorities so that federal action could be instituted against the shipper.

In some instances in this 1932–1933 drive it was found that where some rail shipments were accompanied by a certificate with three or four varieties of apples in the same car, one or more of the varieties would exceed the tolerance. This made us rather skeptical of those first certificates. As a result, our sampling campaign was carried on regardless of whether or not accompanied by a certificate.

A brief summary of the work of that season is of interest:

No. of Boxes Represented by Samples				
Oct.–Nov.	*Dec.*	*Jan.*	*Feb.*	*Mar.*
37,000	15,600	21,000	15,500	11,000
Per Cent Bearing Excessive Spray Residue				
20	15	2.4	12	13

Prior to the 1933–1934 shipping season, the Montana regulation requiring certificates was given considerable publicity both in Montana and in Washington. We also declared ourselves ready to continue our sampling campaign and to take action against all shipments exceeding the federal tolerance.

About that time the State of Washington established a system of packing-house supervision. Each lot of fruit as it went through the washers and was packed was given a lot number. Each lot was sampled and analyzed for spray residue. All lots found exceeding the tolerance were required to be rewashed and brought within the tolerance before they could be sold. As a result there has been practically no trouble with excessive spray residue fruit in Montana since the fall of 1933.

SUMMARY

From the large amount of apples and pears found on the Montana market in the fall of 1932 we believed Montana was being used by some out-of-state fruit growers or shippers, as dumping ground for those fruits exceeding the federal tolerance for spray residue. Through coöperation of the Federal Food and Drug Administration and the Montana State Horticultural Department a sampling campaign was instituted and all fruits found exceeding the tolerance were destroyed or held until satisfactorily treated to bring them within the tolerance. A regulation was passed requiring that all fruits and vegetables shipped into Montana be within the federal tolerance for spray residues and carry a certificate that such produce did comply. Shipments without certificates could at the discretion of the inspector be refused entry or ordered held until an analysis could be made. Local fruit dealers were first inclined to object, but after the death of a 15 year old Billings girl in the spring of 1933, attributed to arsenical poisoning from eating spray-residue-bearing fruit, no more complaints were received about our campaign against such fruit. We

are still carrying on, and again this year have the entire coöperation of the Horticultural Department, and whenever interstate shipments are found exceeding the federal tolerance, samples will be submitted to the federal department so the shipper may be prosecuted.

We believe we have eliminated, so far as possible with the funds and personnel available, this danger to the health of the people of Montana.

Dr. Arthur J. Cramp

WE regret to announce that Dr. Arthur J. Cramp, for 29 years the head of the Bureau of Investigation of the A.M.A., has resigned because of ill health.

The medical profession owes much to him for his relentless fight on quackery. He developed the Propaganda and Reform Department of the A.M.A., which is now known as the Bureau of Investigation.

This Association and our *Journal* owes much to Dr. Cramp, as he was always liberal with his time and advice concerning advertisements and irregulars who approached us. His *Nostrums and Quackery* is known practically all over the world. It is now undergoing its revision for the third edition.

Dr. Cramp was born in England, and came to this country at the age of 19. He graduated in Medicine at the Wisconsin College of Physicians and Surgeons, in Milwaukee, but soon gave up practice and became a member of the staff of the A.M.A. We wish for him all good things in his retirement and as great a degree of health and happiness as is possible. M. P. R.

Poisonous Substances in Food, Particularly Spray Residue on Fruits and Vegetables*

From the Point of View of the City Health Officer

J. C. GEIGER, M.D., F.A.P.H.A., GEORGE H. BECKER, M.D., AND A. B. CROWLEY

Department of Public Health, San Francisco, Calif.

THE subject of food poisoning, whether chemical or bacteriological, is an ever increasing and troublesome problem to health officers. In the course of the investigation of any and all food poisoning outbreaks, health officers should be alert to the possibilities of chemical poisoning. A list of the better known mineral chemical poisons that not infrequently are found in the responsible food, introduced unintentionally or inadvertently in the process of manufacture or preparation, includes arsenic, antimony, lead, zinc, copper, and possibly tin and aluminum, at least under certain favorable circumstances.

A celebrated epidemic of "peripheral neuritis" which occurred in England in the latter part of 1900 was traced to the presence of dangerous quantities of arsenic in beer. Approximately 6,000 persons were affected, and some 70 deaths resulted. The arsenic had its source in sulphuric acid used to hydrolize the starch to make glucose and invert sugar.

Lead is a familiar and dangerous poison, and repeated exposure has long been recognized as a serious public health hazard. Despite the publicity given to the danger of the use of lead piping in water supplies, especially when these supplies are chlorinated, we still find lead service pipes in use in some of our American cities. The recent occurrence of lead poisoning in a number of steel workers employed in the erection of one of the San Francisco Bay bridges was found to be partially due to ingestion of lead with cold lunches. The noonday meal was usually consumed on the job, and there were no washing facilities available.

Food products received in interstate commerce are subject to the scrutiny of the Federal Food and Drug Administration Inspection Service. It is generally agreed that this service is an efficient, indispensable adjunct to state and local public health activities. Federal supervision is not applicable to those foodstuffs entering only intrastate traffic and commerce, but the courteous coöperation extended by this branch of the federal government to local authorities is always of material assistance in state and local food problems. In a number of instances the seizure and condemnation of locally manu-

* Read at a Joint Session of the Association of Dairy, Food, and Drug Officials and the Health Officers and Food and Nutrition Sections of the American Public Health Association, at the Sixty-fourth Annual Meeting in Milwaukee, Wis., October 9, 1935.

factured products have been due to the continuous contact maintained between the district office of the Federal Food and Drug Administration and the Department of Public Health of San Francisco.

Poisoning from consumption of fruits and vegetables containing spray residue presents a problem to the public health official. In the endless battle against insects, fruits and vegetables are sprayed or dusted with insecticidal agents which remain in varying amounts as residue. Unless such residues are removed, the foods reach the consumer carrying quantities of toxic substances which are seldom large enough to cause acute poisoning, but which, over a period of time, may lead to a definite impairment of health due to the cumulative effect.

Since acute poisoning due to the spray residue is not frequently encountered, and since chronic cumulative effects are produced, sometimes even after years the public health aspects of the spray residue problem become a subject of practical importance. It is important because of the definite possibility of mass poisoning, and equally so because the very nature of chronic poisoning is such that it is often difficult, if not impossible, to connect the end result with the causative agent.

Because of the obvious economic and practical importance of food to our welfare, the protection of various fruit and vegetable crops, through the development and application of suitable insecticides particularly, has become a problem of great magnitude. In these control measures against the plant and insect parasites, however, we are confronted with a dual problem: (1) there is the necessity for an efficient insecticide; and (2) we are faced with the public health problem which requires the use of an insecticide uncomplicated by a health hazard.

To attempt complete or partial prohibition of those insecticides in use at present, most of which contain substances toxic to the human organism, would be impossible. Agriculturists and insecticide manufacturers are in a position to propound seemingly sound and convincing arguments against such a move. Some farmers and fruit growers insist that there is no danger whatsoever from these metallic sprays, and demand evidence of death attributable to the residues therefrom. These individuals rely, of course, on the fact that the poisoning is not of the acute but of the chronic type. Growers, in the majority of instances, do not appreciate the dangers of cumulative poisoning.

The solution of the dual problem requires the thorough pharmacologic investigation of all newly discovered or proposed insecticides from the point of view of toxicity to man, regardless of high insecticidal efficiency. Continued research to replace insecticides dangerous to man by materials less dangerous is of the utmost importance. Meanwhile, the public is being exposed to potential health hazards which must be minimized by continued and even more rigorous enforcement of control measures.

Proper tolerance limits for spray residues containing the various agents now considered hazardous must be maintained. The setting of tolerance limits for such toxic agents as lead, arsenic, and fluorine compounds does not entirely guarantee the complete absence of health impairment in the population. This is exemplified by a recent incident in a large city in California. An Oriental grower shipped a truck load of cauliflower to the open market where it was placed on sale. Inspectors became suspicious of the vegetable and took samples, which were found to contain 15/100 grain of arsenic and 4/10 grain of lead per pound, or respectively 15 and 20 times the tol-

erance limits allowed by the United States Government. The alertness of inspectors prevented the sale and consumption of this particular lot, but the fact remains that farm produce does filter into our markets containing large amounts of dangerous spray residue, and one can safely assume that a certain number of similar shipments probably escape detection many times each year. Farm produce entering intrastate commerce should receive more serious consideration, and goods sold directly from producer to consumer should be given closer inspection. This practice should be particularly followed in the case of markets maintained by farmers on well traveled highways in close proximity to metropolitan areas and catering to the motoring public.

The relationship of insecticidal residue to the public health in its various aspects is not always easy to establish by means of experimental evidence, but attention may be drawn to certain possibilities which will indicate the inherent complications and difficulties. The toxic effects of materials such as lead and arsenic may be additive if not synergistic. One chemical agent may increase an individual's susceptibility to another chemical agent. Such chemical agents may not directly interfere with growth, longevity or health, but may lower efficiency and resistance to infection and predispose to disease. They may be the cause of disturbing subjective symptoms. In some cases the agents themselves actually cause specific disease states; as, for instance, the palsies produced by lead and the dental defects produced by fluorides. Definite scientific proofs of such defects may be difficult to establish but they are potentialities that deserve consideration.

Sufficient data exist on chronic intoxication of various kinds to indicate that the public health hazard involved in the use of insecticides is worthy of the most serious attention. We cannot wage a battle against the insects with utter disregard of the effects of that warfare on man.

The Philosophy of Epidemics

NOTHING is worse for a community than long periods of apparent freedom from the endemic infections, though some people consider this as evidence of good public health administration. I have said on many occasions that a periodic epidemic of scarlet fever of the mild type which has been universal for the last decade is distinctly favourable for the health of a population, and I shall maintain further that periodic prevalence of the endemic infections at short intervals is highly desirable, for symbiosis between man and his endemic parasites is persistent and unalterable, and unless the communal immunity is kept up by continuous activity of the parasites, the field in which they work when they are introduced is highly detrimental to the hosts.—Dr. Dunstan Brewer, Swindon. —*Pub. Health,* Jan., 1936, p. 159.

DISCUSSION

FRED W. TANNER, PH.D.
Professor of Bacteriology, University of Illinois, Urbana, Ill.

ANY discussion which involves the use of the term "poison" will lack precision because of difficulties of definition of the term. Substances which are poisonous in the usual sense in certain concentrations become innocuous and even stimulants in lower concentrations. Preservation and conservation of foodstuffs according to present-day methods make it difficult to keep them absolutely free from foreign substances. Some of the latter are of little public health significance in themselves but others, such as certain heavy metals and metalloids, have caused some concern.

The interesting papers which have been presented in this symposium have discussed the significance of lead and arsenic on fruits and vegetables from the viewpoint of federal, state, and city health officers. We have not heard the viewpoint of the grower or horticulturist. These health officials who have spoken, however, are familiar with the serious problem confronting the producers and are sympathetic with the economic considerations necessitating these practices which ultimately may affect consumer health in an adverse manner. While there can be no compromise as far as public health is concerned, we should, nevertheless, keep the fact clearly in mind that spraying practices are employed by producers in the control of worm and insect infestation of their crops, not by malicious intent, but purely from the standpoint of practical expediency. Further, it should be remembered that crop failures due to pest infestation have decided economic bearings, not only upon the producers, but also upon the consumer, by virtue of the fact that short crops invariably cause higher retail food prices. For families or persons in limited circumstances, such a situation can conceivably have a distinct bearing on the plane of nutrition on which they are able to maintain themselves.

To complicate the problem further, it would appear that the consumer, as well as others interested in safe fruit and vegetables, might have to choose between products sprayed with insecticides and a very limited crop (if any at all) of unsprayed infested products. In either case, food and drug control officials are required to seize and condemn the products. I am informed that federal officials are just now greatly concerned over the presence of worms and insects in tomato products. Such contamination is just as objectionable in other vegetables as in fruits. Unfortunately, the best method now available for prevention of infested vegetables or fruits involves the problem of possible health hazards to those who consume these foods.

In view of these facts, the problem appears to resolve itself into:

1. A search for insecticides which are poisonous for insects but not for human beings when consumed in amounts which might be found on foods such as apples, for example. Agriculturists would gladly turn to other substances than lead arsenate if they could be proved to be equally effective. As far as the speaker knows, no such substances have been found. They may be found in the future. For instance, nicotine while somewhat satisfactory, has not given results equal

to those obtained by lead arsenate. While some organic compounds, notably rotenone, have given some promise, they have not been developed to the point where they may be considered as reliable as the arsenates because of certain chemical characteristics.

2. Selection of spraying schedules which would leave only small residues of lead and arsenic on the sprayed crops.

Spraying schedules have been determined largely in the past by the number of broods of insects which must be destroyed. Cost of the poison and expenses of application have in general prevented unnecessary treatment but this has not always been the case. In the section of Illinois from which I come, apples are sometimes sprayed 7 times in a season and further south they may be sprayed 10 times. The last treatment may be given only a month before the crop is harvested. Such apples carry very considerable quantities of arsenic and lead (*e.g.*, 0.25 to 0.50 grain Pb and 0.10 to 0.25 grain As_2O_3 per pound).

3. Development of methods of washing which remove lead and arsenic residues to values below the amount within the stated federal tolerance.

4. Abandoning orchards or fields in areas where spraying schedules require application of lead arsenate very late in the growing season.

Before this problem can be solved to the satisfaction of the various groups which are interested, the following points must be considered:

1. Whether or not cases of poisoning have actually occurred from the ingestion of foods, apples in particular, which have been subjected to proper spraying schedules and subsequently given a washing treatment. There have been no cases of chronic lead poisoning in spite of large residues of lead arsenate which have been found on apples.

2. The types of methods which should be used to determine the amounts of toxic metal contamination on sprayed and/or washed foods. The literature indicates some evident differences of opinion on accuracy of results secured with certain methods employing varied principles for the determination of the metal in question. This situation should be settled by a comprehensive investigation using standard samples.

3. The methods of sampling should be such as to give not only a cross-sectional sample but also accurate history of truck and carloads of fruits and vegetables.

4. The rate at which these metals are absorbed and the effect of the rate at which food passes through the alimentary tract on absorption, should receive further study.

5. The animal species to be employed in toxicological studies should be decided upon with particular reference to the degree to which results on test animals can be translated to human cases. The advisability of the use of human volunteers should receive some consideration, as well as the type of test to which humans might be safely subjected in order to obtain significant data on the health hazard of spray residues.

6. The efficacy of home preparation methods on reduction of the spray residue hazard should be given consideration.

7. The adequacy or inadequacy of the present tolerances for lead and arsenic should be investigated. Such tolerances should have some relation to the amount which would cause illness when the food is eaten. This phase has not been investigated to my knowledge. Experiments in which food containing amounts of metal on both sides of the tolerance fed to human beings, if possible, might yield much valuable information. There should be accurate data on which an acceptable tolerance could be based.

8. The extent to which the metallic components of sprays may be absorbed by way of root or foliage and appear within the fruit or vegetable tissue by virtue of metabolic processes of the plant, should receive further study.

9. The order of toxicity of arsenic and/or lead which might appear in edibile tissues in foods by virtue of metabolic processes should be determined.

H. M. NEWELL

Division of Markets, State of Illinois, Urbana, Ill.

I AM in charge of the Division of Markets in the State of Illinois and not officially connected with pure food regulatory work, but in that Division we are very vitally interested in this spray residue problem.

Illinois has no law which the officials think can be used as a basis for establishment of a spray residue tolerance. Our Attorney-General's Department has given us an informal opinion to that effect. There are some individuals who feel that under our present law we could establish and enforce tolerances.

All that we are doing at present is attacking the problem from a different angle. We are making progress toward producing and shipping cleaner fruit. The Federal Food and Drug Administration has seized during the past few years a large number of shipments of apples from Illinois, and our growers, of course, are very much exercised about that. They came to the Division of Markets for help and we started our work primarily to assist them in solving their problem.

Our plan is this: We have 4 field laboratories in our producing regions. Growers may bring samples of their fruit in for analysis and get the information in regard to what the load is on their samples. If they wish an official certificate on the sample, we will send an inspector to their packing-house, collect that sample, and an official certificate will be issued. To date, most of the growers have brought in their own samples.

Our growers are taking a very active interest in this problem and are making strenuous efforts in most cases to meet the tolerance. I think a great part of this interest has come about through education on the part of the Division of Markets' officials and State Horticultural Society officials. For the past two or three years, we have been urging the growers to put themselves in position to comply with the tolerances regardless of whether or not we had intrastate tolerances. We have pointed out to them that when their fruit is clean enough to be shipped in interstate commerce without danger of seizure they are in an advantageous position from a market viewpoint, whereas if they cannot move it outside of the state, they are bound to meet a lower market due to the fact that many small growers in the state cannot clean their fruit, and, therefore, it is not safe to ship outside of the state.

We are trying to get the situation so straightened out that we can have some state regulation. The matter may require a special act of our legislature to establish tolerances. In general, I feel, however, that we are making very definite progress toward cleaner fruit.

HUNTINGTON WILLIAMS, M.D., DR.P.H.

Commissioner of Health, Baltimore, Md.

I WISH that all the city and state health officers that belong to the Health Officers Section could have been here today. I think the absence of most of them shows plainly that they are not especially interested in this problem in the way that many of us wish they were. Perhaps it is because of different legal set-ups in different states and cities as to the control of

the food problems of this kind, but health officers certainly will not be able to ignore very long the pressing problems that must come before them in connection with poisoning hazards of the kind that lead and arsenic seem to point for the future, and I imagine they will have to change and make adaptations to the needs of the day.

In our city and state we have a very fine connection with the state health authorities, which goes back to the organization of the State Board of Health in 1874, which, after all, is a rather modern development from the City Health Department which goes back to 1797. I am especially glad to see Dr. Sullivan, State Food and Drug Commissioner of Maryland, here, because his department and the City Health Department have been in the very closest affiliation, and the two departments have been in close touch with Mr. Frisbie, who often visits us. The City Health Commissioner of Baltimore is an *ex-officio* member of the State Board of Health.

In the City Health Department, Ferdinand Korff is Director of Food Control. He has prepared this brief paper or rather, summary, of the Baltimore City efforts since 1931:

With the inauguration of the Baltimore Conference in 1932 where federal, state and city food control officials in the vicinity of Baltimore discussed their particular problems at periodic meetings, and the reviewing of current literature in a Journal Club organized within the Department of Health of Baltimore, specific attention was directed to the presence of hazards of spray residues on fruit and vegetables entering Baltimore.

At about the same time a large shipment of cabbages had been received in Baltimore, on which the inspection personnel of the City Health Department observed a greyish powder. The shipment was traced to a local railroad terminus and came from South Carolina. Samples showed the unbelievable amount of 20 grains of arsenic per pound of cabbage. Federal and state food control officials in Baltimore were informed of these findings and the Baltimore Station of the U. S. Food and Drug Administration advised through their coöperating agencies that an investigation be made of the growing areas in South Carolina. A number of the commercial food groups in the city were notified by telephone of the presence of arsenic on the cabbage, and all hampers were returned immediately to the original cars at the railroad station. Seizure was made immediately by the City Health Department and by the Federal Marshal.

Beginning 1932, each of the regulatory food agencies located in Baltimore—federal, state and city—assigned to themselves certain ports of entry of food in Baltimore. Railroad terminals were visited by inspectors of the U. S. Food and Drug Administration; truck shipments and wholesale commission warehouses were visited by City Health Department inspectors between midnight and early morning hours. State inspectors watched over growing areas within the state proper.

Since 1932 all analyses of fruits and vegetables made in the laboratory of the Baltimore City Health Department are reported to the Baltimore Station of the Federal Food and Drug Administration. Weekly surveys are made of the commission merchant district and retail markets where samples of fruits and vegetables are purchased for laboratory examination. Approximately 175 samples are obtained per year by the City Health Department alone, and an equal or greater number by both federal and state officials within the city of Baltimore. In 1935 there were found only 2 shipments which contained amounts of arsenic above the tolerance set by the U. S. Department of Agriculture—a portion of a carload of beans, and a shipment of quinces which was seized by the Federal Marshal. In 1935, determinations were made of lead as well as arsenic and traces of lead and arsenic below the tolerance set by the U. S. Department of Agriculture are present on the majority of fruits and vegetables coming into Baltimore, warranting continued surveillance of interstate as well as intrastate shipments of such foods.

Health officers cannot ignore these problems. They are hitched up with this whole problem of food poisoning outbreaks which crop up overnight, and very often leave the health officer without a suitable answer or explanation.

Wherever it is possible, an answer

is given to the problem, and in our city we have what we refer to as a "Food Poisoning Team." It is made up for the purpose of studying food poisoning outbreaks. It is composed of the Director of the Bureau of Food Control, the Director of the Bureau of Communicable Diseases, the Epidemiologist, the Director of the Bureau of Milk Control, and the Director of the Vital Statistics Bureau. Whenever there is a telephone or a news report of food poisoning, each official assumes responsibility of clearing his particular product or bureau of responsibility by field inspections and epidemiological investigations. The question of these spray residues is not so very different from other types of food poisoning due to chemicals which now and then confront a health officer.

Some time ago we had many people suffering with "ptomaine poisoning" which was traced to silver polish containing cyanide used in many big hotels. The product has been taken off the market.

Fluoride in roach powder is another problem. Dr. Felsen of New York has described fluoride poisoning from roach powder that had gotten mixed up with foods. This matter of food poisoning is very closely allied to the problem of spray residues.

ROE E. REMINGTON, PH.D.

Charleston, S. C.

I WANT to ask Mr. Frisbie if any progress has been made in this certification plan among the vegetable growers whose crops cannot be cleaned as compared with those that can be cleaned, and where the certification plan would be practical as applied to crops of that nature.

WALTER S. FRISBIE

Washington, D. C.

WE have not any plan to certificate vegetable crops. There is a different situation here. For example, we had trouble with celery a few years ago because of excess arsenic. We found there was no necessity for the use of arsenates as there are other insecticides that are effective and which contain neither arsenic nor lead. Therefore, we do not recognize a tolerance for either arsenic or lead in celery. The same is true with certain other vegetables.

Practical Application of an Industrial Health Appraisal Form*

LEVERETT D. BRISTOL, M.D., Dr.P.H., F.A.P.H.A.
Health Director, American Telephone and Telegraph Company, New York, N. Y.

AT the Annual Meeting of the American Public Health Association in Washington, D. C., October, 1932, the writer presented a paper before the Industrial Hygiene Section on, "An Appraisal Form for Industrial Health Service," in which he outlined briefly a preliminary and tentative form which later was published in the *American Journal of Public Health*.[1] This form was further elaborated by the writer [2] at a meeting of the American Management Association in 1933, while in 1934 an appraisal form was suggested to cover the special details of industrial accident and occupational disease prevention work.[3] The original appraisal form for industrial health service was referred in its preliminary and tentative state of development to the Committee on Administrative Practice of the American Public Health Association by the Section on Industrial Hygiene.

COMMITTEE ON INDUSTRIAL HEALTH APPRAISAL

In November, 1932, the Committee on Administrative Practice created a Sub-Committee on Industrial Health Appraisal and 11 members representing various public health and industrial organizations were appointed to study and follow the experimental use of the preliminary form. On the basis of group experience and judgment it was hoped that such a form might be revised, standardized, and officially adopted. In the original meetings of this sub-committee it was agreed that the members should promote the use of the preliminary and tentative form in the industries which they represented and, further, should encourage its use by other organizations so far as possible. Moreover, it was the opinion of the sub-committee that the preliminary and tentative form first should be applied in at least 10 or 12 industries of different sizes and types; and that after this practical application, with comments and criticisms from individuals who had used the form, the committee should go over the entire matter and, if it seemed desirable and feasible, should revise and standardize the form in such a manner as to represent actual industrial experience and group judgment.

TRIAL APPRAISALS

Due largely to the fact that all industrial personnel services, particularly those involving health activities, have been at a very low ebb during the last 2 or 3 years, only 7 trial appraisals have been available to date. The consensus of opinion of the sub-committee is that more trial appraisals should be obtained before proceeding to stand-

* Read before the Industrial Hygiene Section of the American Public Health Association at the Sixty-fourth Annual Meeting in Milwaukee, Wis., October 8, 1935.

TABLE I

BRIEF SUMMARY OF SECTIONS, SUBDIVISIONS AND ASSIGNED VALUES OF PROPOSED HEALTH APPRAISAL FORM FOR LARGER INDUSTRIES AND SUMMARIZED RESULTS OF TRIAL SCORING BY THREE COMPANIES

Sections and Subdivisions	*Original Assigned Values*	*Company Scores*		
		Company A	*Company B*	*Company C*
A. Vital Statistics Activities	75	72.6	17	47
1. Death Records	2	2	2	1

32. Special Health Publicity Activities	5	5	0	5
	1,000	802.55	751.5	758

ardize or adopt any form. Inability to obtain more trial health appraisals from various industries undoubtedly is due to the fact that the times are not particularly conducive to the stimulation of such health studies, surveys, and appraisals among industrial organizations. When business conditions further improve, it is hoped that the industrial health appraisal idea and plan may take more definite shape. In the meantime, in an attempt further to stimulate thought and action on this subject, the writer wishes to call attention to the practical experimental trial of the health appraisal form in three associated companies of the Bell Telephone System.

ORGANIZATIONS COVERED IN STUDY

In view of the experimental and somewhat confidential nature of these preliminary trial appraisals, the three companies will be referred to in this paper as "Company A," "Company B," and "Company C," rather than by their usual business names. Company A covers one of the smaller states and, as of December 31, 1934, had a working force of 4,453 persons of whom 2,502 were women and 1,951 were men. The territory of Company B covers one of the larger states. This organization, on the same date, had a total of 16,789 employees, of whom 7,155 were men and 9,634 were women. Company C has a territory covering several states. The last employee census of Company C showed a total of 21,356; of this number 13,381 were women and 7,975 were men. Responsibility for stimulating health and safety activities throughout each company as well as administering the benefit and medical program for employees rests with a vice-president or other official in charge of personnel and public relations, with the assistance of his department associates, lay or medical. To these companies and individuals, appreciation and gratitude are expressed for the time and effort involved in obtaining these trial appraisals and making them available for this presentation. Thanks also are due for various comments and suggestions which have been given with reference to possible minor additions or changes in the appraisal form. These will be helpful to the committee in the further consideration of the subject.

SUMMARY OF COMPANY HEALTH APPRAISALS

The limited time and scope of this paper will not permit of a complete, detailed statement of the methods and results of each survey and appraisal as applied to the three companies. For this reason only a brief summary of the health appraisals of these companies will be attempted.

Table I gives a condensed summary of the sections, subdivisions, and assigned values of the original proposed *Health Appraisal Form for Larger Industries,* as well as the summarized results of the trial scoring made by the three companies mentioned above. In each case the time covered by the survey and appraisal was for the last complete year of record previous to the making of the study. For Companies B and C it is the first and only appraisal made to date. In the case of Company A, the appraisal figures given in Table I represent the latest, or second, survey and appraisal of the company health program. Their first appraisal, made a year or so previous, showed a total score of 745. In other words, since its first appraisal this company has shown progress in the further development of its health program, and undoubtedly the other two companies would show much the same progress on their second appraisal.

INTERPRETIVE COMMENTS

It would be premature and unwar-

ranted to attempt at this time any specific comparison of the appraisal results of these three companies so far as their total performance or effort is concerned. As a matter of fact, the chief initial objective of such appraisals is not so much to compare one company with another as it is to point out to each company the value of self-analysis in order that it may see wherein it may further improve its health service as compared with a somewhat ideal program. In passing, it may be suggested, however, that it is wholly creditable for any industrial organization on its initial health survey and appraisal to be able to say that its health service is covering three-quarters or more of all those things which might reasonably be expected to be done under the most ideal program. Moreover, it is interesting to note that three somewhat widely separated companies are, on the whole, carrying on health programs of approximately equal value, although showing some small variations in the details of their activities.

Vital Statistics Activities—So far as the gathering of vital statistics and the keeping of records are concerned, each one of the three companies apparently is doing all that might be expected, although in two of the companies more might be done in the interpretation and use of their statistical records of employees. Accurate and systematic record-keeping of employee deaths, sickness, and accidents, as well as of industrial health services and activities, are fundamental for any satisfactory and objective appraisal. Many industrial organizations actually would be unable to make a survey or appraisal of value because of the lack of suitable reports and records; such companies may find it necessary and desirable to concentrate at the outset on the development of an adequate recording and reporting system.

Communicable Disease Control—In the control of communicable diseases the appraisals of these three companies indicate that more attention possibly might be given to requirements for the specific immunization of employees against smallpox, typhoid, and diphtheria. While the control of such diseases rests largely with the community health authorities, industrial organizations may do much to assist the public agencies in this respect by including attention to this subject in their own industrial health programs.

Tuberculosis Control—It is apparent from these trial surveys and appraisals that the control of tuberculosis among industrial employees is receiving considerable attention. That there is room in many organizations for additional effort in reference to prompt and adequate medical, nursing, and institutional care of cases is evident. Early physical examinations and diagnosis and the more complete and extensive examination of employee contacts are among the necessary requirements in the further development of the tuberculosis program in industry. In industry, as with the public in general, the questions should repeatedly be asked with reference to the case of tuberculosis: From whom did he get it? To whom has he given it? Dealing with the immediate case itself is paying attention to only one-third of the problem! Tuberculosis still is a leading cause of sickness among industrial workers, particularly of the younger age groups.

Occupational Disease and Accident Control—It is evident that these three companies were thoroughly alive to the importance of this subject. While there is no special occupational disease hazard associated with the work of the companies studied, and hence no requirement for an active program for the control of such diseases, all three companies have been engaged in well organized accident prevention cam-

paigns. In fact, safety work in industry has become in general one of the outstanding features and accomplishments of the entire personnel and operating services.

In the standardization and adoption of an official industrial health appraisal form it will be necessary to give further attention to this section on occupational disease and accident control, especially from the standpoint of those industries having recognized disease hazards. The questions might well be asked: Should an industry that has no special occupational disease hazard be scored under this section other than for its accident prevention work? Should an industry which has serious occupational disease hazards be given special credit if all control measures are carried out according to the appraisal form?

As indicated previously, the writer recently revised the section on Occupational Disease and Accident Control, in a paper [3] entitled, "Measuring the Industrial Safety Program." The appraisals of the three companies under consideration, however, were made on the basis of the original set-up of this section.

Personal and Environmental Hygiene—While the three companies show fairly equivalent *total* scores with reference to their programs having to do with personal and environmental hygiene of workers, they do differ considerably in the details of their efforts and performance as regards specific services and activities. It is evident that these companies, as undoubtedly is the case so far as most industrial organizations are concerned, have developed fairly adequate programs for the promotion of environmental hygiene, including all those factors having to do with general and special sanitation, safety equipment, lighting, heating, ventilation, and food and milk control in lunch-rooms and cafeterias. Just as the newer public health has stressed individual personal hygiene, so also must a newer industrial health place greater emphasis on the physical and mental condition of the individual worker. This means that more attention in the future must be focused on: (a) various types of medical examinations, preëmployment and periodic; (b) seeing that the employee gets the right type of medical, nursing, nutritional, or institutional care that he or she may require; (c) better follow-up and supervision of sickness and accident cases; (d) adequate health and safety education of the individual workers; and (e) personal *health* supervision somewhat analogous to the very efficient *safety* supervision that has become a part of all enlightened industrial policies and practices. This involves the extensive training of supervisory employees on all matters pertaining to health.

General Health Publicity—The three companies in question have carried on fairly complete general publicity in the interest of health, particularly as regards articles on health subjects in company magazines and the use of health bulletins and reports. There apparently is need for additional effort in the field of visual education and publicity through the valuable media of posters and moving pictures.

OPINION AS TO VALUE OF FORM

In closing, the opinion of one company representative may be quoted as to the value and practicability of an *Industrial Health Appraisal Form:*

> From observation and study of the form, I believe that it can accomplish, or provide a very definite aid toward the accomplishment of the objectives sought, namely.
>
> 1. To obtain a picture of the extent or degree of organization and development of modern industrial health practice in a company or any unit of the same.
>
> 2. To serve as an instrument to promote, guide, interpret, and measure health work in an industry or any of its units.

3. To arouse interest on the part of all company officials in the need for adequate health service in the industry; and to present those more directly in charge of the management of any unit with a tangible and concrete form of objective.

4. To provide stimulus for the development of a well balanced industrial health program, and to supply standard indices by which progress in health work may be followed by company personnel.

The extent to which such a form may be expected to gain these ends will no doubt depend upon a number of factors: the size, nature, and personnel policy of the business; the type of its employees; their home and outside interests; environment; etc. In addition, from the administrative point of view, the use of the appraisal form may accomplish something further, scarcely less important in any well rounded industrial health program. By classifying and evaluating each health policy or activity, it correlates many previously dissociated ideas in connection with our health programs and objectives. Each separate item may therefore be viewed in terms of its relationship to the entire health betterment job rather than as a detached and perhaps doubtful experiment.

Jungle Yellow Fever

ONE ready rule in the early days was to ascertain first of all whether the stegomyia mosquito was present in a given area where men were suffering from yellow fever. If that mosquito was not present, yellow fever was ruled out. It now appears that this rule is not universally applicable. It has come to be recognized that yellow fever may exist, not only in a mild and almost unrecognizable form, but also in forms not associated with its recognized carrier, the stegomyia mosquito. The disease is transmitted and perpetuated in certain endemic areas by vectors different from the single one (stegomyia mosquito) encountered in Havana, Panama, and epidemic cities in general. Within these endemic areas, large parts of which are covered by jungle, there occurs yellow fever not carried by that mosquito and therefore offering to the scientific investigator new and as yet unsolved problems.

Among other things this means that in these areas the control of yellow fever through the customary attach on the stegomyia mosquito is inapplicable. It does not, however, mean that former methods of control were erroneous, because in coastal areas and in large cities which were formerly threatened by yellow fever the disease is carried by the stegomyia, and measures against this mosquito continue to be both cogent and necessary.

Since the strict correlation between the yellow fever mosquito—*aedes aegypti,* or stegomyia—and yellow fever can no longer be maintained, we now have some inkling of the reason why complete elimination of yellow fever from the large cities through destruction of mosquitoes was not necessarily followed by the disappearance of the disease from tributary rural areas. These rural areas themselves constitute a new and different problem. As the result of antistegomyia measures the disease has disappeared so far as urban outbreaks are concerned, and the next step will be to concentrate on the comparatively unknown jungle yellow fever.—The Rockefeller Foundation *Annual Report*, 1934, page 27.

Typhoid Carriers*

A Study of Their Disease Producing Potentialities Over a Series of Years as Indicated by a Study of Cases

GAYLORD W. ANDERSON, M.D., F.A.P.H.A., ANGELINE D. HAMBLEN AND HELEN M. SMITH

Massachusetts Department of Health, Boston, Mass.

THE decline of typhoid fever, brought about by the growth of public water supplies and improved milk and shellfish sanitation, has left a "residual typhoid," caused apparently by typhoid carriers. In a community such as Massachusetts it is a fair statement to say that water- and milk-borne typhoid have become so rare, and have been so for the past few years, as to constitute an insignificant fraction of the total typhoid in the state. Little of the decline during this period and probably in the years to come, can be attributed to further improvements along these lines, so that the typhoid carrier becomes of increasing importance in the problem of reducing the "residual typhoid." The purpose of this paper is to study some of the factors that have underlain the decline in carrier-borne typhoid.

Table I presents the typhoid mortality rates for Massachusetts since 1875. The same data plotted on a logarithmic scale are presented in Figure I. The striking decline during the latter part of the last century and early years of this century was due almost wholly to the improvement in public water supplies, the curve of decline of typhoid almost matching that for the decrease of population not served by these supplies. Since about 1910 there has been no such improvement in the water supplies as would explain the even sharper decline in typhoid death rate. Unquestionably much of the improvement during the years 1910–1925 was due to milk sanitation, notably the advent of pasteurization, but here also the decline has been too striking to be explained solely on such a basis. It is obvious, therefore, that the principal decline in typhoid of recent years has been due, not to improved water supplies or better milk sanitation, but to factors affecting the principal reservoirs of the present-day typhoid infection, *viz.*, the carriers.

It has long been recognized by epidemiologists that the control of typhoid fever through the elimination of water-borne outbreaks has meant inevitably a decline in the incidence of the disease that would make itself manifest over a long period of years. Thus any substantial decline in typhoid fever during any period of time results in the production of fewer typhoid carriers

* Read before the Epidemiology Section of the American Public Health Association at the Sixty-fourth Annual Meeting in Milwaukee, Wis., October 7, 1935.

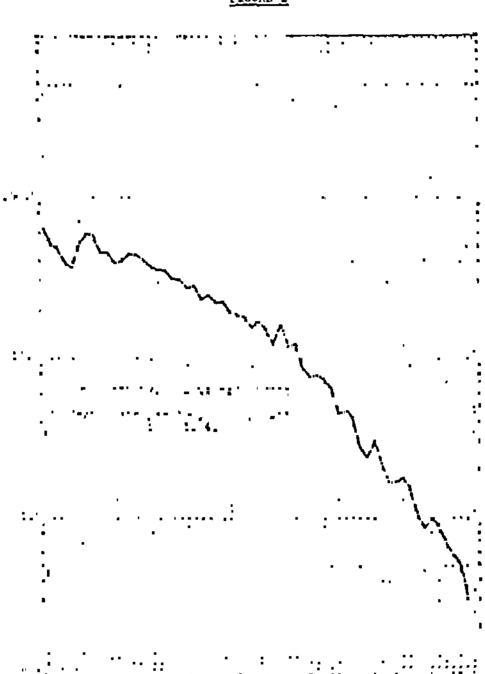
than in the previous epoch. As years elapse and these carriers die from other diseases, we find an accelerated sterilization of the population with respect to typhoid carriers. Thus in a community such as Massachusetts in which there has been a steady decline in typhoid fever for over 70 years, many more carriers die in a single year than are produced in that same year. Each year leaves the community, regardless of any active public health measures for carrier detection, with fewer sources of infection than were present during the preceding year. It might, therefore, be inferred that the decline in typhoid from year to year was an exact function of this decrease in number of living carriers. That such an inference gives far from a true picture of the situation will be evident from consideration of the ensuing graphs and tables.

For the purpose of this paper, all typhoid morbidity in Massachusetts has been calculated as a constant function of the death rate. Thus it has been assumed that throughout the period under study typhoid fever has consistently had a 10 per cent case fatality rate, so that the number of cases in any year has been 10 times the number of deaths. That such an assumption is justified is shown by the unchanged case fatality rates in the larger hospitals, coupled with the commonly accepted fact that, aside from the dietary regimen, there has been no outstanding advance in typhoid therapy for several generations. The use of death figures has eliminated any error due to variations in adequacy of case reporting, the death returns in Massachusetts having been reasonably complete throughout the period in question. Using this method for calculating morbidity, it can then be assumed that the number of survivors from typhoid fever in any year was 9 times the number of reported deaths.

It has further been assumed that 2

FIGURE I



per cent of those that recovered from typhoid continued as carriers the duration of their lives. Such a figure has been reported by one of us[1] as that found over a period of years in Massachusetts, and has been confirmed for New York by Ramsey.[2] That the rate of carrier production should be higher has been claimed by Havens[3] and by Garbat.[4] It is immaterial to the present problem, however, whether the rate is 2 or 10 per cent or any intervening figure, as any error introduced would apply equally throughout the calculations and thus automatically be eliminated. Consequently the number of carriers produced in any single year has been calculated as 2 per cent of the survivors in that year. It is thus possible to estimate theoretically the number of carriers that have been produced in any period of time. Table II shows the calculated number of carriers produced in Massachusetts since 1875.

To determine the number of carriers in a given population at a given time is impossible for many reasons. An approximation to this figure may, however, be made by determining the average age of typhoid fever patients over a period of years and, knowing the average expectation of life at any age and the carrier production rate, calculate roughly the number of carriers now living. Thus if it be assumed that the average age of typhoid patients has been constantly about 20 years (there has been no significant change in the age distribution of typhoid deaths for over 60 years), and that the expectation of life at age 20 has been 40 years, it would be assumed that the number of carriers in the population today was represented by those who had become carriers during the past 40 years. This is at best a very rough calculation, as it makes no allowance for the age distribution of the cases with varying expectations of life

(Cont. p. 400)

can it mean that as years pass environmental factors that formerly were responsible for much typhoid fever have so improved. There has been no such change in Massachusetts as would account for the sharply downward trend in typhoid fever during recent years. That the carriers should have become so progressively more careful in their personal habits seems also entirely unbelievable.

A more likely explanation is to be found in the enviroment of the carrier. So much attention has been paid to the individual carrier that far too little attention has been given to the accessory factors that lead to a new infection. Anderson and Mack [5] showed that for a case of typhoid to develop from a carrier, a series of separate events must take place in regular succession, and that if the chain of events were broken in any link the new infection would not develop. One of these variable factors is the ingestion of the typhoid organisms by a susceptible host, and to this might be added the condition that these germs be in sufficient number to produce the disease.

Keeping in mind the importance of the environment of the carrier, we may examine Tables IV and V. These show by years the time that had elapsed since infection before the carrier was recognized, what might be called the "carrier age" of the carrier. There

have been excluded from the tables those carriers who were recognized during their convalescence, and were thus afforded no opportunity to produce infections, and those who were unaware of a previous typhoid infection. The tables include only those carriers who were discovered through investigation of cases of typhoid, and were thus found to have been sources of infection. The tables thus represent the number of years that had elapsed between a known typhoid infection and the production of further cases. It is at once apparent from the tables that many more carriers have been detected within 10 years of their own infection than during any other decade of their carrier life. The surprising uniformity of data for other states (Table V) adds support to the data in Table IV, the slight difference in Michigan being hardly significant.

Such a finding is quite at variance with the current concept which too often pictures a carrier as one who had typhoid 20 to 40 years ago. So frequently is this concept encountered that some have even suggested that a carrier might enter a latent phase a few years after infection, subsequently as gall-bladder inflammation developed, entering an active phase, and thus causing infections. The figures of Tables IV and V hardly support such a hypothesis. The figures are even more striking when thought of in terms of the potential number of carriers available for discovery. It is obvious from Figure I showing the decline of typhoid in Massachusetts that there have always been throughout the period studied fewer persons in the community who had typhoid during the past 10 years than in the next preceding decade (10–19 years prior). It is thus all the more striking to find that the majority of the carriers have been found in that group that had actually the fewest number of carriers. We have thus a paradoxical situation of finding more carriers where fewer exist, and finding the fewest where the most exist.

The explanation for this paradox may be sought in the environment of the carrier. Table VI shows the relationship to the carrier of the individual whose infection prompted the investigation that led to the recognition of the carriers.

The family contacts represent those

(2) Wealthy family with maid.
(3) Wealthy families with maids.

normally members of the carrier's household, while the casual contacts include relatives, visitors, and friends who had not been in constant contact with the carrier throughout the period since the carrier's infection. The "maid contacts" represent those infected by a maid found to be a carrier, though in each case the maid had been in the environment less than 5 years. The milk and food contacts include those instances in which the carrier was found to be handling milk or food for sale, thus representing an extremely casual and infrequent contact between the carrier and victim. It is significant that in the few instances in which a carrier had infected a family contact after 10 years of carrier life, the carrier was a man who would have less contact with food, or a member of a wealthy family where presumably the food was usually handled by servants. It is readily apparent that those carriers who were found within a few years after their own infection had infected members of their immediate households, and that as years elapsed those infected were progressively less intimately connected.

That as the years elapsed members of the immediate family were not infected has not meant, however, that all of them have had recognizable typhoid infection. On the contrary, the majority have had no such illness. That they have acquired a resistance to the disease can be inferred from the fact that they escaped apparent infection at the time of infection of a visitor or new arrival in the household. This can only mean, therefore, that there has been over a period of years a gradual immunization of these family contacts. It is thus to be concluded that a carrier if undiscovered will in a period of years either infect or immunize the normal immediate environment, and that subsequent infections are conditioned by the introduction of susceptible new material into the carrier's environment or sphere of influence. This is then the apparent explanation for the shift in the ratio between the number of cases in any year and the number of carriers produced in the preceding periods of years. It offers a reasonable explanation for the rather surprising fact pointed out above that the number of cases in any year was not a constant function of the number of carriers in the community but rather of the number of carriers produced during the preceding 5 to 10 years.

COMMENT

If the conclusions here drawn as to the importance of the first few years of the carrier-life of a typhoid carrier be correct, they constitute a very powerful argument for more adequate and rigorous supervision of all cases of typhoid fever as potential carriers. It affords no support to the attitude so often encountered that carrier detection and supervision is ineffective because it reaches so small a fraction of the total number of carriers in the community. The data here presented suggest, however, that all carriers are not of equal importance, those that have recently become carriers being of greater public health importance, not because of factors inherent in the carrier but because of the relative susceptibility of the environment surrounding the carrier. The carrier who has been such for many years has either so infected or immunized the immediate environment that new cases will not develop until fresh susceptible material is introduced. Such a situation develops with the arrival of a visitor or is presented when a carrier in middle or late life suddenly loses the normal means of livelihood and seeks a food handling position. In such a manner the carrier who has raised a family without apparent infection suddenly produces cases in the new susceptible environment. Whether or not this new environment be infected with clinically recognizable disease or develops a latent immunity may well depend on the magnitude of the infecting dose conveyed at various times by the carrier.

CONCLUSIONS

1. The incidence of residual (carrier-borne) typhoid fever in a given community is not a constant function of the total number of carriers in the community.

2. The incidence of residual (carrier-borne) typhoid fever in a given community is a function of the number of carriers produced during the preceding 5 to 10 years. This explains the rapid decline in the incidence of the residual typhoid after water-borne and milk-borne infections have been eliminated or reduced to a minimum.

3. Most carriers infect or immunize their immediate environment within a few years (5 to 10), subsequent cases developing principally among the new susceptible material introduced into this environment.

Escherichia Coli as an Indicator of Fecal Pollution in Oysters and Oyster Waters*

C. A. PERRY, Sc.D., F.A.P.H.A., and
MILWARD BAYLISS, Ph.D.

Bureau of Bacteriology, Maryland State Department of Health, Baltimore, Md.

IN this paper data are presented which should indicate the relative value of *Escherichia coli* and the colon group as indicators of significant fecal pollution. While the discussion is concerned only with fresh shell oysters, the question of a more specific indicator of significant fecal pollution than the colon group is of even more importance in the examination of market oysters. Obviously the same problem exists whether the object is to determine fecal pollution in shell oysters or market oysters. Market oysters are, after all, the same oysters except for handling and storage. Those members of the colon group which confuse the examination as to pollution in shell oysters confuse it even more perhaps in market oysters because these are often subject to non-fecal contamination from dirty equipment and are subsequently held. The result is that colon group types (not *Escherichia coli*) are found in excessive numbers, though they probably have no more significance as indicators of significant fecal pollution than a total colony count of bacteria.

The question of whether *Escherichia coli* or the colon group should be used as a basis for estimating pollution in oysters and other mollusks is a broad one of the utmost importance, for the colon group has been found confusing and unreliable, and some means of determining probable fecal pollution is essential as a check on the certification system, as a test for market oysters and for oysters taken from waters in which they grow or in which they are temporarily placed.

During the 10 years 1925 to 1935, thousands of samples of oysters and oyster waters (oysters 4,152, oyster waters 12,689) have been collected from the 20 different oyster areas into which the Chesapeake Bay, Md., has been divided. These data have already been studied extensively and have been the basis for several special reports by various members of the staff of the Maryland State Department of Health.[1, 2, 3] The one inescapable fact in these studies has been the lack of any significance which may be attached to individual oyster scores as indicators of pollution. So useless have oyster scores been found for this purpose that an agreement between those concerned was arrived at about 18 months ago to discontinue the oyster scores on the basis of the colon group in the sanitary oyster survey in Maryland and to test

* Read at the Joint Session of the Laboratory, Food and Nutrition, and Public Health Engineering Sections of the American Public Health Association at the Sixty-fourth Annual Meeting in Milwaukee, Wis., October 8, 1935.

the value of *Escherichia coli* as an indicator of fecal pollution. During the past 2 years 1,463 samples of oysters and oyster waters have been examined for both their *Escherichia coli* and colon group scores.

The term *Escherichia coli* is construed as indicating any member of the colon group which is unable to grow in Koser's citrate medium. Such organisms are invariably methyl red positive, Voges-Proskauer negative, produce indol, cannot ferment cellobiose, and produce gas in suitable media at 46° C.

Examinations for *Escherichia coli* were made using both the modified Eijkman medium of Perry and Hajna [4] and standard lactose broth, as presumptive tests. Determinations for the colon group were made in accordance with the standard procedures of the American Public Health Association. A report of this work up to January 1, 1935, has been given in the *Journal* for June, 1935. The Eijkman test in its present form has been found so superior to lactose broth as a presumptive test for the isolation of *Escherichia coli* from oysters and oyster waters, that it is being recommended for trial in other laboratories in consideration of its inclusion as part of a new standard procedure for the examination of shellfish.

Through a grant from the American Public Health Association, it has been possible to compile and study the more than 1,000 *Escherichia coli* results, and more than 4,500 colon group results from certain oyster areas in Maryland. An attempt has been made to present these data in a way that should show directly what correlation, if any, there is between quantitative *Escherichia coli* and colon group concentrations in oysters and oyster waters and pollution as judged from sanitary survey data. The data have been studied in two ways. In one approach, the average number of *Escherichia coli* and colon group organisms for a number of sampling stations were "spotted" on sanitary survey maps for the Choptank, Chester, Severn, and Patuxent Rivers in Maryland. In this way, the relationship both of *Escherichia coli* and the colon group to known pollution could be studied.*

No extensive comments on the significance of these data are necessary. The important point is the close agreement evident between the concentration of *Escherichia coli* in oysters and observed pollution. In order to make this relationship clearer in some respects, the data for the 4 rivers were also prepared in linear fashion; that is, the rivers were straightened out and the data summarized for mile sections and studied in relation to the principal sources of pollution. It is unfortunate that a larger number of *Escherichia coli* results as well as those for more sampling stations were not available. It is believed, however, that in spite of the comparatively small number of *Escherichia coli* results (1,463—see footnote Table I) available at the time, they do attest the superior value of this organism as an indicator of significant fecal pollution.

An attempt to clarify further the relationship between pollution in oysters and oyster waters as judged from sanitary survey information and as expressed by *Escherichia coli* and the colon group has been by giving average concentrations of *Escherichia coli* and the colon group organisms for pollution classified as "not significant," "slight," "moderate," and "heavy." (See Table I.) While it is impossible to classify accurately pollution at sampling stations on the basis of sanitary survey data alone as "not significant," "slight," "moderate," or "heavy," it is possible to do this in a roughly accurate manner.

* It has been found impossible to reduce the size of these maps to that suitable for inclusion in this article.

Such a method has afforded the only approach to an evaluation of the bacteriological data. If the classification could have been more accurately made on other than bacteriological grounds, the data would be more convincing. Pollution varies for any sampling station with tides, weather, and temperature. The biology of the oyster further complicates the relationship and makes and accurate evaluation difficult.

in the oysters are still very high, but *Escherichia coli* is practically absent.

Temperature affects greatly the number of colon group organisms present in both oysters and water. During the summer months when the temperature of the water rises above 50° F., there is a large increase in the colon group in both water and oysters. In oysters this increase may be enormous. When the temperature of the water is below 50° F., the concentration of colon group approaches that of the *Escherichia coli*, but during the summer, the non-fecal types of the colon group apparently find a most suitable environment for multiplication, probably due to organic matter present. The environment in the oyster is doubtless even more suitable, and results in high colon group scores on oysters taken during the period of active feeding. It is possible that *Escherichia coli* may also increase somewhat both in water and oysters when the temperatures of the water are unusually high, but water temperatures are always relatively low for the growth of this organism, and this, together with its inability to utilize carbon from organic matter (as indicated by its inability to use carbon from citrate and other organic salts) places it in an unfavorable environment for multiplica-

Colon Group determinations: Oysters 1,451, Water 3,877, Total, 5,328

In general, the classification of a sampling station as not significantly, slightly, moderately, or heavily polluted, was based on the proximity to towns, sewers, privies, and on the population of towns, type of sewage disposal, and the volume of water. In the Chester River for example, the major source of pollution is from Chestertown, a town of more than 2,800 population with untreated sewage. A secondary source of pollution is Centerville (population 1,291) on the Corsica River, a tributary of the Chester River. Very little, if any, pollution from Centerville reaches the Chester River. The only oysters showing any significant pollution on the basis of *Escherichia coli* are those from the upper part of the river nearest Chestertown. In the lower part of the river, many miles from any pollution, concentrations of colon group organisms

tion. The data presented show that *Escherichia coli* tends to disappear gradually as self purification occurs, while the non-fecal colon group types increase. This is in agreement with the observations recently reported on the Whangpoo River in China.[5]

It will be noted in Table I that the average *Escherichia coli* (most probable number per 100 c.c.) results for 422 samples of oysters from waters judged to be without any significant pollution, is 4.5, the average for 230 samples from slightly polluted waters was 49, while the average of those from moderately polluted water (97 samples) was 196 and heavily polluted (30 samples) 167. In contrast to this, there is little if any difference in the average results based on the colon group. In oysters from heavily polluted waters the average was 1,509 against 1,634 for moderately polluted waters, 1,979 for only slightly polluted waters, and 1,158 for waters free of any noteworthy pollution. There is, therefore, a close agreement between pollution as observed and as expressed quantitatively by *Escherichia coli* for oysters. On the basis of the colon group, no such correlation exists.

For oyster waters there is rather a nice transition from 1.5 *Escherichia coli* per 100 c.c. in unpolluted water, to 5.5 for only slightly polluted, to 36 for moderately polluted, and to 67 for heavily polluted water. These numbers seem in much closer agreement than the colon group results which are 61, 100, 134, and 376 respectively. It might be inferred from these figures that the *Escherichia coli* results indicate a lowering of the margin of safety. That this is not true is attested by the fact that more individual *Escherichia coli* have been recovered from fresh raw sewage where the Eijkman presumptive test has been used than total colon group types where lactose broth was used as a presumptive test.[6] *Escherichia coli*, as has been repeatedly demonstrated, constitutes over 95 per cent of the colon group types found in fresh human feces. The increase in the colon group both in water and oysters may be considered, therefore, to indicate that self purification is going on. The colon group tends to distort and magnify the picture of real pollution in water while in oysters it may indicate gross pollution where there is none.

A more specific idea of the magnitude of the differences between the numbers of *Escherichia coli* and of colon group organisms in oysters may be obtained from Table II. The results from individual samples indicate the enormous differences between the number of *Escherichia coli* and of colon group organisms which frequently occur, and the greater efficiency of the presumptive Eijkman test over lactose broth for the isolation of *Escherichia coli*. The data are representative of those obtained during the warmer months when the temperature of the Chesapeake Bay water is above 50° F. (April to November) and especially when the temperature is above 70° F. (June to September). The degree of pollution as judged from sanitary survey information is also given. The data indicate a relative correlation between the most probable numbers of *Escherichia coli* and a lack of such correlation on the basis of the colon group.

Colony counts of bacteria growing at 37° C. on standard nutrient agar were also studied. These counts have been found to parallel the concentration of colon group bacteria and to indicate pollution in a general and similar manner.

SUMMARY AND CONCLUSIONS

Data are presented for the concentration of *Escherichia coli* and the colon group in oysters and oyster waters for

the Choptank, Chester, Severn, and Patuxent Rivers, in Maryland, together with sanitary survey information. No significant correlation between the concentration of colon group bacteria in oysters and various degrees of pollution has been found in any of the areas studied. In the case of oyster waters, there is a fair correlation between the concentration of colon group bacteria and pollution. During the summer months there is a large increase of colon group bacteria in both water and oysters. Enormous increases in the colon group content of oysters are found when the water is warm, in both grossly polluted and relatively unpolluted areas. If, therefore, the quality of oysters was determined, especially when the temperature of the growing waters was relatively high, and on the basis of the colon group, those from waters of unquestionable purity would in many instances be judged as grossly polluted. The colon group cannot, therefore, be relied upon to indicate significant fecal pollution in oysters.

A close correlation has, however, been found between the concentration of *Escherichia coli* in both oysters and water and the amount of pollution. The results indicate that *Escherichia*

coli is superior to the colon group as an indicator of significant fecal pollution in both oysters and oyster waters.

Laboratory Control of Water Purification Plants*

HARRY E. JORDAN, F.A.P.H.A.
Chemical Engineer, Indianapolis Water Company, Indianapolis, Ind.

WE who are engaged in the control of public water supplies do not know everything about the quality of water, but enough is known to build and operate purification plants so that public water supplies are seldom unsafe. The phrase, "enough is known," must be taken precisely at its real content. The reference is to the state of knowledge; not to the application of that knowledge, because it is fairly evident that, in recent years, whenever a public water supply has not met all of the requirements of safety to the consumers, the failure was not due to the lack of knowledge. It was occasionally due to the lack or inavailability of equipment, but more often due to the simple failure of a responsible personnel to use its knowledge and the equipment intelligently.

We may properly digress for a time into a discussion of problems of water works personnel—problems associated with its frequent lack of training and often with the lack of real interest. One of the interesting developments of recent years has been that, in many plants over the country, the men engaged in water supply operations are taking voluntary training when the requirements of the state in which they work do not make it necessary. The fact that only 3 states at the beginning of this year required that their purification plant operators be regularly trained and licensed is in itself evidence of the fact that the people, since the first glow of interest in sanitary progress at the beginning of the century, have settled back into a state of complacency and lack interest in the training and qualifications of public service personnel, especially those associated with the vital task of public water supply.

Again, lack of interest on the part of water works operators that frequently interferes with the proper operation of purification plants, is purely a by-product of the political control under which so many water works plants operators work. Men in charge of properties, or divisions of water works departments, are in operating positions not because of any fitness for the work, but because they happen to be, shall we say, precinct committeemen of the victorious political party.

These impediments to the application of the knowledge that we have of the adequate control of water purification plants, affect the content of this discussion, but are somewhat tangential. The title is "Laboratory Control of Water Purification Plants." Fortunately for our purposes, Webster defines the laboratory as "the workroom of a chemist." That introduces pre-

* Read before the Laboratory Section of the American Public Health Association at the Sixty-fourth Annual Meeting in Milwaukee, Wis., October 8, 1935.

cisely the idea that is essential to the consideration of this topic. The entire purification plant is the workroom of the chemist. A purification plant is a laboratory that cannot be separately directed. I was somewhat amazed a to receive a communication from the head of a water department of a city of over 100,000 population, saying that a campaign was being waged by a consulting laboratory in his community to obtain a contract to carry on the laboratory work of his purification plant. The rejoinder is obvious to me, that if the water department wished to contract for the operation of a purification plant with a consulting concern, the operation to include definite and complete control, with certain criteria as to costs, etc., in the contract, the proposal might be entertained, but to detach the laboratory control from the routine operation of a purification plant is inconceivable. The spirit of the water works laboratory must be the spirit of intelligently trained curiosity, and the moving spirit of a purification plant must be the application of that training and intelligent curiosity in an attitude of never being quite satisfied that things are right until they have been shown to be right.

That type of control starts with the moment that the raw water enters a plant. The first observation is that of the visible physical load, or turbidity, of the raw water. The referee contact with this observation may be carried on in the laboratory, but the practical hour to hour performance (and the performance must be from hour to hour and not from day to day) should be in the hands of shift employees. They can be trained to do the work, especially if they know that their work is being adequately and frequently checked by the laboratory staff.

The next step is the performance of simple field tests as to the adequacy of preliminary treatment. When Streeter's research indicated to all of us that practically two-thirds of the bacterial removal in the purification plant was effected before the water went to the filters, it should have made plain that the importance of control of preliminary operations needs to be emphasized. These field tests may be so simple as the trial filtration of the coagulated water to see that the finely divided material has been collected in the floc. The process may be extended to jar stirring tests, with varied doses of coagulant. They may even go so far as combination of these latter tests with tests for residual alumina. Wherever a test of this type is made, the control laboratory should do no more than referee the performance of those tests by the shift operators, or the laboratory should be staffed and in direct contact with the operators every hour of the day. Relatively few plants need to indulge in the latter type of organization. The great majority of plants are operated and the tests are adequately made by reasonably intelligent workmen. Performance of tests according to a definite outlined routine must be required at regular intervals on every shift.

The next very valuable piece of field mechanism is the simple turbidimeter (Tyndall ray type indicator) so well developed by Bayliss in his work at Baltimore. This has an amazing capacity to indicate deviations from normal performance on the part of filter units and to flash emphatically to the eye and mind of an operator that something has occurred to break down the satisfactory performance of the sand layer. Its use does not require college training. The men simply need to be taught to correlate the indications given with past performance of the plant. In a purification plant where normal performance results in a turbidity of about 1/10 p.p.m., a deviation only up to ½ p.p.m. will be very evident, and

while the average consumer will have no knowledge of the change, and while it is unlikely that such change will have any adverse physiological effect upon the consuming public, the deviation is indicative of the immediate necessity of reviewing the purification processes which have preceded this stage in the treatment.

By and large, the average plant performance will produce a safe drinking water if the indication given by the fine turbidimeter is good, and if the next observation, that of the amount of residual chlorine, is regularly made and adequately controlled. There is the strong fortress of plant control. A great deal of attention in the forthcoming edition of *Standard Methods* has been given to the determination of chlorine. The precision, or attempted precision, of statement of this test is designed to meet the needs of the laboratory, but in the day to day control of purification plants, if the laboratory reviews the hourly observations of residual chlorine at least once a day and correlates the plant observations with the laboratory records, the field tests do not need to be carried on with the precision that should be expected in the laboratory. At the same time, the field tests probably have a more direct bearing on the overall efficiency of plant operations than do the laboratory tests. When it is stated that the field tests do not need to be performed with the precision required of a laboratory test, one does not imply that basic considerations as to reasonable accuracy in handling reagents, reasonable cleanliness of apparatus, reasonable care in the handling of samples, should not be fulfilled. It is not implied that anyone can neglect the care of the orthotolidine solution, or expose reagents, standards and test samples to direct sunlight, nor by any means should one neglect to hold the sample treated with orthotolodine in the dark until the color development is complete. These important phases of the chlorine test can be just as well understood by the shift men as by the expert chemist.

It is necessary to confess a considerable degree of astonishment at the fact that, in spite of the directions in previous issues of *Standard Methods* against exposure to sunlight, many laboratories have been found to carry on all of their work and keep their permanent standards in the direct sunlight. Occasionally, one is led to think that possibly the simpler minded laborer of the plant could be used to read *Standard Methods* to the trained chemist, so as to be sure that the latter paid attention to all of the detail that he should.

We have travelled through a purification plant controlling the preliminary treatment of the water, observing the residual turbidity after filtration and checking the efficiency of chlorination. Perhaps some of you will be shocked when it is implied that many of the other tests which we all make are "window dressing." That term is used to irritate some of you. Every operating test beyond the above brief list should be examined in the light of this question—"Just what does it contribute to the successful operation of the plant?"

Obviously, if ammonia or carbon treatment is being used for taste improvement, and if prechlorination is practised, the laboratory staff will add to its daily routine the task of reviewing, by odor and associated tests, the efficiency of the dosage. Set dosages and foolish economy produce consumer bad will. Set dosages at focl-proof high rates waste money. The laboratory naturally must balance needs with dosage.

The field of historical record of plant performance is the establishment of bench marks by which the value of the field tests above enumerated can be de-

termined. We will probably all agree upon the bacteriological record as the principal one that meets this need.

Shall that record include an enumeration of the bacteria? Koch's rule No. 2 was "To allow a complete and constant control of the bacterial efficiency of filtration, the filtrate from each single filter must be examined daily." The simplest record form which this examination can take is that of the bacterial count. At the same time it is likely to be indicative of all the facts that one needs to know about the individual filter. Is its performance equal to that of the other units? Has there been some misadventure in the sand layer? The 37° count will reasonably answer those questions. Shall we apply the 37° count to finished water and to distribution samples? The answer is in the affirmative, but not for the reason that would probably be given by many. The enumeration of bacteria in distribution samples frequently evidences lack of circulation, if the count is high. Lack of circulation might result in unpleasant tastes and odor, causing consumer complaints. The bacterial increase is likely to occur before the taste and odor develop. As a means of determining the hygienic efficiency of filtration, it is doubtful that the bacterial count has great value. With other conditions unchanged, there is considerable evidence that with a bacteria count in finished water of 10 or 100 or 1,000, no consumer reaction will result. The tradition persists that high counts are associated with lack of safety. High counts of heterogeneous organisms probably indicate improper operating control. High counts of homogeneous groups of organisms may indicate a simple unloading, or too long storage, or too little draft from a main.

When we make an estimate of the presence and density of members of the coli-aerogenes group, we are building up the historical record that is most serviceable as a bench mark in plant operation. To what extent should coli-aerogenes records be accumulated? Under present-day conditions one can reasonably expect of a well controlled purification plant that an accurate record of coli-aerogenes density under all load conditions in the raw water, especially the peak loading, be made. One can also assume that with a somewhat lesser degree of accuracy, water in the various intermediate processes of purification should be checked. The filter effluent before final chlorination should, in the United States, be checked with the Treasury Standards, namely, the examination of five 10 ml. portions, to the end that, as a general operating result, the filtered water before final chlorination meets the requirements of the Treasury Standard. In other words, there should be a shade of disappointment on the part of the plant superintendent if the efficiency of the prior phases of the purification process has not been great enough to make chlorination unnecessary, except as a final extra factor of safety. The water as delivered by the plant should not only be examined, in the United States, in the five 10 ml. portions of the Treasury Standard, but also an equal number of 100 ml. portions should be examined. The reason is that if the plant operator sets as his yard-stick the simple terms of the Treasury Standard, he has no data aside from compliance or noncompliance with the standard. If, however, he sets as his yard-stick the absence of coli-aerogenes organisms from the great majority of the 100 ml. portions examined, he not alone has an added feeling of assurance, but when deviations occur that indicate the presence of the group in the 100 ml. portions, they should occur before such deviations would appear in the 10 ml. portions, thus an opportunity may be given to review and correct the

faults in the procedure that led to the deviation in the larger samples examined. The finished water plantings should also extend to an equal number of 1 ml. portions. Only in this way will an adequate appraisal of maximum density be had when and if some misadventure reduces the normal efficiency of operation.

An intelligent operator who feels the weight of his responsibility to the thousands of people dependent upon him for safe water will not omit any finding of fact that, even temporarily unpleasant, eventually adds to the records that make future operation safer. The useful working tool given laboratory workers by the option of confirmation of coli-aerogenes by planting in selective liquid media makes possible the production of a greater volume of mathematically defensible records. With the development of correlative data that indicate the close approximation of the confirmed technic adopted with the full complete test, the operator will find himself in a position to appraise more intelligently the significance of steps in plant operation in the terms of coli-aerogenes density.

American practice with relation to coli-aerogenes group definition puts a somewhat higher requirement upon water supply methods than is common to many other countries. We are all familiar with the discussion that has gone on for a number of years with relation to the use of certain selective media for primary planting of water samples. The broad implication of the use of lactose broth, as contrasted with selective broths, is that by using the former, not only are certain coli-aerogenes forms that are frequently called "attenuated" included in the findings, but also a class of organisms which probably are not essentially associated with human sewage pollution but with processes of destruction of vegetation. If the goal is set of removing all these from the finished water, instead of removing only the definite fecal strains of coli, the hygienic quality of the supply automatically becomes higher. Certain studies in this country have indicated that the sanitary survey correlates better with the coli-aerogenes findings from primary planting in a selective medium than with similar findings from primary planting in the more catholic lactose broth. In other words, it is evident that definitely bad sanitary backgrounds of samples are associated with positive findings in the selective media, and that the routine process in this country includes those doubtful cases of sanitary surveys where perhaps there is no specific evidence that could be correlated with the presence of the coli-aerogenes group.

But can we not agree that those border-line conditions should be improved? American water supply practice has met fairly well the financial and physical requirements necessary under the present method of measuring water quality, and while the correlation of the sanitary survey may be a bit more definite, if the other method is followed, it is also evident that the degree of protection to the consumer against adverse conditions would be lessened just in the degree that the laboratory control of water supplies narrowed itself to search for more specific organisms. Perhaps when political control of water departments is not so obvious, when the training of purification plant operators is more widely insisted upon, and when a shade more knowledge is at hand as to the precise meaning of some of the tests we make, it may be possible to narrow the category of organisms that we call coli-aerogenes; but that time is not yet here.

We have mentally travelled through the purification plant; observed the shift men making many necessary

routine tests vital to good performance; we have set up the technically trained staff as a referee group, principally engaged in training and maintaining the efficiency of the operator as a bench chemist. We have observed that the technical staff, in making additional tests, has made them because each one had been shown to contribute definitely to the excellence of performance of the plant. They have also made records in terms of bacterial efficiency, and have correlated these records with the simple field tests. What else is there for the technical staff to do? A great deal. They are engaged in research studies preparing to meet the problems of tomorrow.

A New Method for Estimating Population

THE March 9 issue of New York State *Health News* describes a new device for estimating population increase:

The population of New York State on July 1, 1935, was 13,226,417 and will increase by July 1, 1936, to 13,345,909, according to a recent estimate by the Division of Vital Statistics, State Department of Health. These figures are based upon the assumption that the relative growth of the population of the cities and counties of the state since the last federal census of 1930 was the same as that of the entire country. The estimates previously employed by the department were computed by the "arithmetical method," which assumes that the annual increase in population after a census is equal to the average annual increase during the last intercensal period. The new estimate for the state for 1935 is less by 468,000 than the estimate formerly used.

The new figures admittedly have the single virtue of being, on the whole, less inaccurate than those hitherto used. The division is now investigating the possibility of a permanent solution of this most important problem through the development of sources of local authentic information, by means of which the estimates could be currently modified in keeping with the movement of population.

Under normal conditions the arithmetical method produces reasonably satisfactory results. The years following 1930, however, were clearly not normal. The growth of the population has definitely slowed down because of the continued decrease in the birth rate and the almost complete cessation of foreign immigration. In the 10 year period 1921–1930 the net immigration averaged over 300,000 a year, while in the 5 year period 1931–1935 the number of aliens who departed from this country exceeded the number of aliens admitted by almost a ¼ million. One has to consider also the important additional fact that as a result of the depression the movement of population within the country has undergone a marked change. In 1930–1933, as a direct consequence of rapidly diminishing opportunities for employment, the hitherto prevalent movement from country into city was reversed. There is reason to believe that because of improvement in the economic situation, the trend after 1933 has again become cityward.

Under these conditions, arithmetical estimates had no longer the degree of dependability that was formerly attached to them. It was felt inadvisable, however, to make any change in the established procedure because there was hope that a federal census might be taken in 1935. This expectation has not materialized and it was therefore necessary to abandon the arithmetical estimates as being entirely too high and misleading. Various experiments led the Division of Vital Statistics to decide, until a better way could be found, to adopt with slight modifications the method developed by the Census Bureau, according to which "the computed increase in the population of the country as a whole [is] distributed among the states, cities, and counties in proportion to the share which each of these areas had in the increase between 1920 and 1930."

TROPICAL MEDICINE IN THE UNITED STATES [1]

IN view of the fact that a large part of this country is semitropical and in close touch with tropical countries, and that for many years we have been scourged with malaria over a large part of the South, and have had all too frequent epidemics of yellow fever, it would seem that the study of tropical diseases would have been taken up earlier than it has been. Indeed, physicians in America did not seem to awaken to the importance of investigating tropical diseases until the appearance of the textbook by Sir Patrick Manson in 1898. Some of this indifference may be ascribed to the lack of knowledge of fundamental facts necessary to intelligent methods of prevention, yet Manson's work on filaria was done in 1878, and Laveran discovered the malarial parasite in 1880.

The Spanish-American War, in 1898, not only brought us into closer touch with tropical countries and their diseases, but put several such countries under our control, and was the beginning of our existence as a world power. The World War further emphasized the necessity of understanding tropical diseases and the methods of guarding against them.

The first organized work on tropical medicine, as far as the United States is concerned, was in 1898. Credit must be given to Surgeon General Sternberg of the Army for the establishment of two Army Medical Research Boards. The one under Major Walter Reed solved the mystery of the transmission of yellow fever and showed that the disease was caused by a filtrable virus. Captain Richard P. Strong organized the Board in the Philippine Islands, which has for 35 years turned out a large amount of valuable information. Two years after the establishment of the Army Board, the government of the Philippines established a Bureau of Science to which Dr. Strong was transferred as head of the biological department.

In March, 1903, the American Society of Tropical Medicine was founded. After 10 years it had 121 active, 18 corresponding, and 37 honorary members; and in 1913, a journal, now known as the *American Journal of Tropical Medicine,*

was established. In 1921, the membership had fallen to 108, and attendance at the meetings averaged from 10 to 20. It now has 429 members, is active, and its meetings are well attended.

Tulane was the first university to establish a Department of Tropical Medicine in a medical school, in 1911. Two years later this was organized as a School of Tropical Medicine and Hygiene, becoming in 1919–1920 again a department. The next Department of Tropical Medicine was established at Harvard Medical School in 1914. In 1913, a Board for the Study of Tropical Diseases was organized in the Medical Department of our Army, with headquarters in Porto Rico, with Major Bailey K. Ashford as President. In 1926, the School of Tropical Medicine at San Juan was established through his influence. It issues the *Porto Rico Journal of Public Health and Tropical Medicine*. In 1928, there was founded at Columbia University the Department of Tropical Medicine as a sub-department of Medicine. In 1929, there was established at the University of California, the Pacific Institute of Tropical Medicine, with Dr. Alfred C. Reed as Director. This list seems to complete the roster of special departments of tropical medicine in the United States, but many medical schools are active in research and teaching, or both.

Vanderbilt University has a strong Department of Preventive Medicine and Public Health from which many contributions on tropical medicine have come. The Department of Parasitology at Johns Hopkins has made a number of studies. George Washington University has given courses in Tropical Medicine continuously since the session of 1907–1908. Our Army and Navy have furnished many excellent studies under men like Edward R. Stitt, Surgeon General, and Captain Charles S. Butler. The studies carried out by Colonel Siler and Major Hitchens, and others, of the Army, have been notable.

The International Health Division of the Rockefeller Foundation has done much to stimulate the study of tropical diseases. Its most notable discoveries have concerned yellow fever. Its workers have transmitted the disease to Rhesus monkeys and to mice, and have developed a practical method of immunization. Thus the remaining mysteries of this dreaded disease have been cleared up, and a wealth of scientific facts have been added to our knowledge.

In 1934, the American Academy of Tropical Medicine was founded. With an active society of tropical medicine and this American Academy, there will be no lack of scientific stimulus to the study of tropical diseases, from which our country will benefit. There is every reason to believe that the interest in tropical diseases by our universities and schools will continue to increase and that greater facilities for study and teaching will be provided.

Our Public Health Service has carried out fairly extensive experiments on the transmission of tropical diseases by mosquitoes transported in airplanes, and two of its officers [2] have developed an efficient fumigant for planes. Since yellow fever is under good control in the tropical countries with which we are in close touch, there is little fear that the disease will be introduced within our borders. Nevertheless, it is comforting to know that our Public Health Service maintains efficient units for the control of this disease and is active in protecting us against introduction through travel routes. In view of fast passenger steamships now on the ocean, the regular airplane service with the tropical countries to the south of us, and a world-wide airplane service being rapidly developed, there is every reason for us to maintain a watchful attitude and to cultivate to its fullest extent the study of tropical diseases.

Being a world power carries responsibilities as well as dangers. Though it seems that we were slow in realizing the importance of tropical diseases to our country, we have now made a good start and may well be proud of the discoveries which American institutions and American men have given to the world in respect to these diseases.

LEST WE FORGET

WE have always been impressed with the similarity between religion and public health. People are apt to be good religiously when they are afraid of death. When there is danger of an epidemic people are good from the health standpoint. The United States once, for a short time, had a national board of health created when we were menaced by a yellow fever epidemic from the tropics at a time when we did not know anything about the spread of the disease. With the passing of this danger, the national board of health as such was allowed to die, though fortunately many of its functions were passed on to what is now our Public Health Service.

Many of us can recall the time when the danger of bovine tuberculosis to human beings was a really live question and gave rise to many controversies. American work in 1901 and 1902 proved the danger, against the opposition of Robert Koch, and some leading American physicians preferred to accept Koch's authority to the proved facts furnished by their own countrymen. Except among the veterinarians and the packers, bovine tuberculosis has not been much discussed for some years. The packers are solely interested in the losses they may sustain due to the disease. The veterinarians are interested in suppressing bovine tuberculosis from the professional as well as the economic standpoints, but the medical profession appears to be singularly indifferent. Health officers in general, both state and city, are still actively interested in the pasteurization of milk, which was brought about chiefly through the proved danger of bovine tuberculosis to children, especially, though there are many other diseases which may be transmitted by milk which are prevented by the process.

The English are more persistent than we are and when a study is begun they carry it through. Since the appointment of the British Royal Commission following the London Congress in 1901, there has been constant study of bovine tuberculosis in England under Governmental grants by well trained men, and their reports are always enlightening. While we were content in this country to say that bovine tuberculosis was apt to produce glandular and bone disease in children, the English persisted in their studies, and have brought to light some 120 cases of pulmonary tuberculosis due to the bovine strain, 40 of which have been observed since 1933, but which Koch said did not occur.

The most recent report[1] gives the histories of two families, in each of which there were multiple cases of pulmonary bovine tuberculosis. In one there were 2 cases of pulmonary disease in adults and 1 of glandular disease in a child. The mother had been a milker and was afterward reported as a case of pulmonary tuberculosis. Of 10 children in the family, 1 died in infancy, 1 had pleurisy with

effusion and infiltration of the right apex, which had cleared up, 2 were among the 3 cases mentioned in the article, and the remainder were healthy. The daughter died, and at autopsy the presence of the bovine strain as the causative organism was confirmed.

In the second case, a man, his wife, and a child were affected. The husband and wife both gave cultures which were below the standard virulence usually found in bovine organisms, the two cultures being identical in character. Gastric lavage done on the 3 children gave a positive result in 1, the organism recovered being again a dysgonic strain, highly virulent for the rabbit. While the history is somewhat involved, the reporters believe that the infection spread from the husband to the wife.

Five cases of familial tuberculosis due to the bovine organism have now been found in England.

We owe much to our Bureau of Animal Industry and the veterinarians working under it. They have kept alive this question of bovine tuberculosis and have given us a considerable number of tuberculosis-free areas and many partial or completely accredited areas. With the pasteurization of milk which is now so general, tuberculosis of bovine origin has decreased to a very gratifying extent, but if our vigilance is relaxed, there is every reason to believe that the disease will increase in cattle, and in corresponding measure be carried to human beings.

PREVENTION OF EXPERIMENTAL POLIOMYELITIS

REASONING by analogy from one species of host to another, or from one infection to another is not always safe or even profitable as a conjecture in communicable diseases. Occasionally, however, valuable leads are obtained in this way. Armstrong and Harrison [1] and Armstrong [2] have published recently continuation of work at the National Institute of Health of the U. S. Public Health Service in which they have used the infection of encephalitis (St. Louis type) in mice as a "feeler" for judging the value of intranasal prophylactic measures against poliomyelitis, the experimental work on poliomyelitis, of course, having been performed on monkeys. These authors' earlier work [3, 4] on the efficacy of sodium alum has been confirmed by Sabin, Olitsky, and Cox [5] who also used tannic acid solutions against poliomyelitis following the earlier work of Olitsky and Cox [6] on the use of tannic acid against nasal instillations of the virus of equine encephalomyelitis in mice. It appears from the more recent work of Armstrong and Harrison that picric acid is safer and somewhat more likely to be effective than alum or tannic acid.

It is to be hoped that uncontrolled application of such agents will not take place until their evaluation for human use can be carried out.

THE 1935–1936 YEAR BOOK

THE words "Desk Copy" have been placed appropriately on the cover of the 1935–1936 *Year Book,* which was distributed with the March *Journal.* Our members may profitably keep it on their desks and at their elbows for constant reference.

The editor was aware as the individual committee reports passed through his hands that they represented some uncommonly fine material. Only when he saw them assembled under one cover, however, did their full importance and significance strike him. This is, in his opinion, the most outstanding collection of committee reports ever presented to the readers of the *Journal.* They are worthy of careful and continuous study. The Sections will be hard pressed to match their excellence next year. They are the summaries and conclusions of many painstaking pieces of work, and the results of unnumbered hours of individual labor, correspondence, and conference. If the last word in group-thinking on pressing public health problems is wanted, the *Year Book* is the first place to look for it.

Further, this *Year Book* is more than a collection of committee reports, valuable as they are. Through the industry of the executive office, several useful lists have been compiled and included. The one which will be most frequently consulted, doubtless, is that of the health officers of the United States—state, city, and full-time county. So far as the last named is concerned, we stand aside for no one on the basis of accuracy, at least, as of the date recorded. Other things published in the *Year Book* for the first time are: a list of universities in the United States and Canada conferring public health degrees, together with brief statements of entrance requirements; a list of American foundations making grants of amounts in excess of $5,000 for medical and public health purposes in 1934; a list of cities surveyed by the American Public Health Association; lists of winning and honorable mention cities and counties in the Rural and City Health Conservation Contests.

The 1935–1936 *Year Book* is veritably a "compendium of useful information." If the membership will respond to the invitation in the foreword and suggest items that may be added next year and in the future, it may be desirable eventually to issue the *Year Book* with the upper left-hand corner punched as is the telephone book so that it may be hung within easy reach for as frequent consultation.

BACK NUMBERS WANTED

Readers of *The American Journal of Public Health* are asked to send unwanted copies of the following issues—

September, 1930
January, 1931
January, 1933

—to the American Public Health Association, 50 West 50th Street, New York, N. Y., as these issues are out of stock.

These will be much appreciated, and reimbursement of postage will be made in each case.

PUBLIC HEALTH EDUCATION*

"More Murderous than Microbes"—Such is poverty. It is brought out in illuminating newspaper reviews of "Why Keep Them Alive?" by Paul de Kruif, published by Harcourt, Brace, New York, N. Y. This is not a review. We have space here only for quoting several paragraphs.

Balanced diets. It's nice to talk about them for your children and mine. But what's the use of talking about a balanced diet to a coal miner with six children, when he hasn't had a chance to get into the mine for months?

It is notorious that our big newspapers will lavish space, will blacken their front pages with headlines about 60 lives lost in a tornado, or a hundred taken in a steamship fire, or a thousand lost in some remote Oriental earthquake; yet they remain almost mute, with a mysterious hush-hush, about the incredibly greater never-ending disseminated disaster, the perpetual emergency of mass maiming, sickening, suffering, dying that is caused by destitution.

Said one reviewer, Lewis Gannett, in *New York Herald-Tribune:*

All over the country, wherever De Kruif wandered, he discovered doctors, nurses, teachers heroically saving lives—and then saw the saved lives being wasted.

As "Shortening" Is to Pie Crust—More shortening makes pie crust richer. See what shortening did for a new play on Broadway, according to *New York Sun* (March 7, 1936):

Five times before "Co-respondent Unknown" opened, it was played before specially invited audiences—dress rehearsals in lieu of an out-of-town opening. The reaction of these audiences indicated that there were certain dead spots which should be eliminated, and accordingly, late in the night, after one of those performances, Kenneth MacKenna, director of the play, and Mildred Harris, co-author, sat over a manuscript with brutal blue pencils poised over the dialogue.

In some speeches perhaps just a word or two were cut. Sometimes the two found it possible to cut a whole speech entirely. Compression went further when occasional whole pages were obliterated, and in one instance a complete scene, taking nearly 4 minutes, was done away with entirely. . . .

To the producers and the playwright, the fact that the play was 10 minutes shorter after 15 minutes of dialogue had been cut was no great puzzle—it was expected. The lines left in the play were so much funnier—because the letting-down poor lines were out—that the laughter of the audience forced the actors to wait until the tumult died down before going on with their lines, at dozens of points throughout the play. In other words, 15 minutes of audience laughter had been added, in place of 10 minutes of superfluous dialogue.

The health educator doesn't need time out for laughs, but he does long for audiences which listen to the end—*and are ready for more another time.*

Cutting words, phrases, or paragraphs—cutting out the "dead spots" in our copy—may turn the trick.

Meaning Something or Other—What the significance to health educators may be we won't attempt to state. An article on "Health Food Fad" tells of

a growing business to help you eat yourself healthy—with a slam for more familiar foods and a profit for somebody.

The article in *Business Week,* 330 W. 42d St., New York, N. Y. (Feb. 29, 1936; *20 cents*), discusses

* Please address questions, samples of printed matter, criticism of anything which appears herein, etc., to Evart G. Routzahn, 130 East 22d St., New York, N. Y.

highly specialized products that promise health and vigor; some that offer relief from everything from anemia to zymosis.

Sample prices: 47 cents for a 3½ oz. can; 2 lb. for $3.69; 45 cents for 16 oz.; 14 oz. of a broth extract for $2.50.

What is wrong with other foods, as well as the unusual qualities of the "health foods" are basic selling talk.

"Live and Let Live"—This is the title of the sixth of a series of annual publications "distributed free in the interest of street and highway safety, and for the promotion of more pleasurable use of automobiles."

It is a 40 page scrapbook of pictures in color, sketches, strip cartoons, page cartoons, statistics, etc.

Copies should reach editorial writers, and all who might write or speak on safety topics, or plan safety measures.

Many pages could be reproduced individually as fliers, or enlarged as posters or as display panels. Several of the pages would do a good job if copied on large painted billboards.

Copies of "Live and Let Live" are supplied free, in letter-sheet size, and pocket-size, as well as a new highway safety test entitled, "What's Wrong." Address: Travelers Insurance Co., Hartford, Conn. They may be able to supply copies of some of the earlier issues of the series.

A New Mark for Health Education in Survey Reports—The recently issued report on public health in Pittsburgh sets a new record in completeness of the reporting on health education. The health education material is made easily accessible through a distinctive, common heading, and by mention in the chapter sub-headings of the table of contents.

One or more paragraphs on "Community Health Instruction" appear in the chapters on control of acute communicable diseases, tuberculosis control, maternity hygiene, infant hygiene, preschool hygiene, school hygiene, venereal disease control, mental hygiene, cancer control, heart disease control. We are confident that nothing like this has been done before. There are no such paragraphs under vital statistics, laboratory service, public health nursing, general sanitation, milk and food control.

To the above, amounting to nearly 3 full pages, is to be added a 5 page chapter on "Community Health Instruction." This sets another high mark in city health survey reports.

We were tempted to quote the whole of the health education material, but will reproduce the two concluding sections which include emphasis on 4 vital points: (1) a basis for planning; (2) a definite and unified program; (3) a trained director of public health education; (4) a representative committee to stimulate coördination of activity and joint program planning.

SUMMARY

The lack of a comprehensive public health education program in Pittsburgh is apparent. Many people are reached by pamphlets, lectures, and motion pictures, but there is a marked deficiency in both verbal and written instruction particularly in connection with venereal diseases, dental hygiene, mental hygiene, and sanitation. The health education activities are not in general planned on the basis of studies of special needs and opportunities in different districts of the city or among special age or racial groups.

The health instruction given in the schools, as discussed in Chapter IX, provides a valuable medium of spreading information regarding matters of community and personal hygiene.

Although some health material appears in the daily newspapers, this valuable channel of instruction could be more extensively and effectively utilized.

There is a considerable amount of community health instruction work being done in Pittsburgh, but it is not coördinated, and is not based on any definite and unified program. Undoubtedly with a closer coördination of activities, much more could be accomplished than at present.

FUTURE PROGRAM

1. In view of the importance of developing an individual and community consciousness in regard to health matters, and to acquaint the public of all classes with the present-day responsibilities and services of the health department, provision should be made in the city department of health for:

a. A trained director of public health instruction.

b. The printing and circulation of a monthly health bulletin and an annual report which would include not only statistical data but interpretation of the city's health services and problems.

2. As soon as the Tuberculosis League can be relieved by the Department of Health of all or a part of the responsibility it has had to assume in the tuberculosis control program, the Tuberculosis League should develop in coöperation with the Department of Health a more extensive health education program.

3. Consideration should be given by official and voluntary health and social agencies, and the Medical Society to the establishment of a health education committee made up of representatives of the organizations in the city now engaged in this work to stimulate coördination of activity and joint program planning.

In *The Appraisal of Public Health Activities in Pittsburgh, Pennsylvania: 1930 and 1933,* by Marian H. Ewalt and Ira V. Hiscock. Bureau of Social Research, Federation of Social Agencies, 519 Smithfield St., Pittsburgh, Pa. 125 pages. Not dated, but issued in 1935. *$1.00.*

Where to Get Motion Pictures—The most helpful publication available on this subject is "Guide to Motion Pictures," edited by Louise Franklin Bache (formerly with Syracuse, N. Y., Health Department), and published by Community Chests and Councils, Inc., 155 East 44th St., New York, N. Y. 46 pages. *50 cents.*

Of the 17 classified lists the following cover health topics; recreation and physical education; general health and sanitation; child health and child care; dental hygiene; nutrition; disease prevention; social hygiene; safety; first aid, disaster relief and nursing; nature study.

The "Guide" is a substantial pamphlet. The pictures listed are largely from authoritative sources. The brief synopses tell more than is to be found in most comprehensive lists, and seem to be as reliable as is possible without examination of the pictures. The typographical arrangement of other essential information makes for easy use. The lack of abc order of picture titles under each topic is a disadvantage.

There are some omissions, both of pictures and sources of information. Will any one who examines the "Guide" please tell the editor of pictures which should have been omitted, or should have been included?

Health Education in December Journal—Certain references in *American Journal of Public Health,* Dec., 1935, are here noted:

In "Public Health a Problem in Distribution" by Brown (page 1287) we have a review of public health situations which all will wish to be acquainted with, in addition to this specific paragraph:

> The inclusion of intelligent public support as an essential to satisfactory public health service needs no justification. Unfortunately, we have not been able to command it to any great degree. All too frequently our support has been based more upon emotion than upon reason because we have concentrated our attention on health service to the individual and neglected to educate him and demand public support for such services. The results have been manifest in the inertia of the public while essential health services, in many places, were either abolished or reduced to a poverty level. We cannot hope to maintain a high degree of health service until we find the way to secure and maintain intelligent public support for our programs.

"Annual Report of Montefiore Hospital" (page 1333) calls attention to

a report in which an institution is "humanized."

Be sure to read "Humanizing Knowledge," page 1358.

"Scientific Exhibits at Milwaukee" (page 1389) reports on 6 displays with citations of their particular merits.

Public Health Education Section is given 4 new members on page 1391.

Health Education in January Journal—Of interest to those concerned with health education are the following references in *American Journal of Public Health*, Jan., 1936:

See "Malaria in the Philippines," by Russell, pages 1–6, for a glimpse of unused scientific information, and for the mention of "time rather than money" as a main factor in some situations.

See "The Health Conservation Contest," by Rankin, pages 13–16; by McCamant, pages 17–19; by Lentz, pages 20–22.

Of course you will read "Precision in the Choice of Health Education Methods," by Shepard and Arfsten, pages 54–58.

Under "Books and Reports" see discussion of the present-day value of the "family medicine book," in review of "Modern Home Medical Adviser," pages 77–78.

New members of Public Health Education Section are listed on page 87.

Scientific Exhibits at New Orleans—Increasing success has marked, at the Annual Meeting, the showing of displays reporting research, illustrating methods or devices, or recording history.

Any one with an idea to propose or a display to offer is invited to write to the A.P.H.A. office in New York.

It would be timely to have displays at New Orleans from A.P.H.A. members in points around the Gulf of Mexico, and further south.

Important to observe: an exhibit is not a satisfactory form for presenting detailed statistical data which can be examined more satisfactorily if offered in mimeographed or printed form.

Reprint and Pass It On—Quite a few articles which appear in the *Journal* would be useful if circulated in non-professional groups. Some would favorably impress a chamber of commerce health committee. Newspaper editorial writers would welcome some reprints. Leaders in divers clubs and associations would be interested by reprints of certain articles. Others should go to the school superintendent, or to principals, or even to the teachers. But a full list of openings would take too much space.

Reprints are supplied at a nominal cost rate. Write promptly for reprints of your own article, or one by another writer.

When you have reprints to spare please send sample to editor of this department. Please tell how many cents a copy should be sent.

Telling about the Hospitals—"Educating the Public About Our Hospitals," by Dr. Allan Craig, is a report of the Committee on Public Education, American Hospital Association. Its 7 large pages include a variety of useful material.

An interesting angle is suggested which others than hospital people may well use (the italics are ours):

> Every doctor and every hospital today is stressing the importance of preventive medicine. Hospital publicity may well point out *the fact that it is old-fashioned to call the doctor only after disease has made its presence known* by pain and suffering. Our most precious possession, health, may best be safeguarded by the proverbial ounce of prevention—which is still worth pounds of cure.

How hospitals may use printed matter:

There is a mass of literature intended for public use which is published by various recognized organizations each year. One of the great difficulties is to get this material into the hands of those to whom it would be of benefit. Every one of our hospitals can, with little added trouble or expense, greatly assist in the solution of this difficult problem.

Why not establish a means for the distribution of this valuable and reliable material in your hospital? A corner may be set aside in the hospital lobby for the exhibition of posters and a reading table provided where pamphlets may be attractively displayed. Suitable literature may be placed in the patient's room for his attention during convalescence. Every hospital has dozens of opportunities for the effective first-hand distribution of good educational literature along the lines of community health.

In *Hospitals*, 18 E. Division St., Chicago, Ill. Mar., 1936. *35 cents.*

Health Education Exhibits at New Orleans—Space has been allotted for a proposed health education exhibit. This to be divided between public health education in any of its specialized forms, or its technics, and school or college health education.

Statements as to what you would like to see, and what you have to offer, will be welcomed in care of the editor of this department of the *Journal*.

A most cordial invitation to participate is extended to members all around the world who are concerned with health education.

The Value of Early Prenatal Care—Dr. Estella F. Warner, Office of Child Hygiene Investigations, U. S. Public Health Service, reports:

Evidence is constantly being sought which would indicate that the various efforts to disseminate public health information are influencing health practices and benefitting the people. One criterion which has been accepted as indicative of the effectiveness of the health education aspects of a maternal hygiene program is the advance made toward obtaining information or care during the early months of pregnancy. For several years the Office of Child Hygiene Investigations has issued a series of 9 prenatal letters upon the request of individuals. No publicity has been given this service and none sought. The material was intended merely to meet the requests received by this office. Nevertheless, approximately 4,000 series are distributed each year. More than 50 per cent of those receiving the letters have replied answering the question as to the month of pregnancy when the request for information was made. Careful check of these replies has been made for the last 3 years. It is interesting to note that in 1933, there were *no* requests for information made by women during their first month of pregnancy while in 1935, 6 per cent of all the requests were received from women in the first month. In 1933, less than 50 per cent (49%) of the requests received were from women who had not yet attained the fifth month of pregnancy, while in 1935, that number had mounted to 64 per cent. Therefore, even in a 3 year period there seems to be evidence that women are becoming more appreciative of the value of prenatal care early in pregnancy and making effort to obtain information.

Are there reports available from similar state or provincial services?

A Health Tabloid—The *New Haven Sunday Register*, Feb. 23, 1936, issued a health tabloid magazine section of 40 pages. The broad field of public and personal health is covered. Signed articles come from health leaders in and out of the state. High points in the health program are featured and deficiencies are emphasized.

The advertisements were subject to approval by officers of the County Medical Society. Not always has such coöperation been possible. Philadelphia, for example, gave up the tabloid idea because the newspaper insisted upon using unapproved advertisements. Should we question the statements which follow, or are such advertising claims so comparatively innocent that they may be accepted by a medical society or health agency.

Health and Purity in home made candy.

Electric Cookery is the most healthful

cooking method the world has ever known.

There is Health Insurance in . . . dairy products.

Insure your Health with . . . washable wall paper.

Quite thoughtfully, Publicity Assistant Paul H. Stevens has secured copies of the tabloid to be sent to the first 50 public health workers who address him at Department of Health, New Haven, Conn.

"What I Read in the Papers"—That's "all I know" said Will Rogers more than once.

And all many people know about medicine is what they learn in the same way. Hence the importance of a competent press relations bureau to the average medical society.

So Dr. Iago Galdston, in *Medical Economics,* has told the county medical societies how to get their say into the newspapers. We quote two paragraphs of generalizations from the close of the article:

Do not censor the news. Do not ask a paper to suppress a news item. Express yourself about it as strongly and as emphatically as you feel warranted, and leave the rest to the editor. If so-and-so claims a cure for cancer, that claim, right or wrong, is news. The editor is obliged to print it. But he will usually be more than willing to begin the news item with some such phrase as "In the face of strong skepticism expressed by the medical profession of Crossway County, Dr. So-and-So today claimed that he had discovered a cure for cancer."

You can trust a reporter (Stanley Walker warns you against the female of the species); but it is best to have your "say" in writing. If you are making a statement over the telephone have it read back to you. In case of an interview, be sure to see the copy before it goes to press; make that a condition of consenting to be interviewed. The world is full of honest mistakes.

"Have You Seen the Papers?" in *Medical Economics,* Rutherford, N. J. Feb., 1936.

It's "Social Disease" in Middletown—Again the Middletown, N. Y., Department of Health illustrates how an effective, inexpensive annual report can be prepared.

The especially clear mimeographing, the humorous illustrations, the conversational text, and the quality and weight of the paper used, make an effective combination.

On the page headed "Social Disease Control" Dr. Shelley says that "present signs are the public may soon cease to be an ostrich about social disease."

Is it possible that Dr. Shelley is needlessly hesitant? Has he slipped "venereal" or "syphilis" just once into a morbidity report to check local reactions?

Dental Hygiene in Canada—The Canadian Dental Hygiene Council is a national voluntary public health body, composed of both laymen and dentists, organized for promoting dental health. It is endorsed by the Canadian Dental Association, and all of the Provincial dental associations. It receives grants from the federal government at Ottawa, the Canadian Life Insurance Officers' Association, the Canadian Oral Prophylactic. Association, and philanthropic bodies.

The annual report for 1935 is entitled "A Poor Life This, If . . ." this being the title of a report from the field secretary. There is a report of a dental health campaign in Prince Edward Island, and another on recent developments in state health insurance in Canada.

The Dominion headquarters is in Medical Arts Building, 170 St. George St., Toronto.

Health Education in Palo Alto—Two of 5 paragraphs under "Education and Publicity" are quoted from the 1935 report of Palo Alto, Calif., Health Department:

The chief avenues employed for distributing health information have been the

schools, the health center and the press. Each home visit of the nurses is used as an opportunity for health propaganda and instruction. Talks by members of the department have been made to clubs and group meetings.

For purposes of the health conservation contest, account has been kept of health articles appearing in the local paper, a total of 1,521 columnar inches of health material appearing during the year. Of this total 827.5 inches represented health articles of local origin. Acknowledgment is made of the valuable assistance of the local newspapers in the publication of health department news and the keeping of contemplated health projects before the people.

Hygeia, February, 1936, Contents—Published at *25 cents* a copy, at 535 N. Dearborn St., Chicago, Ill.

Infantile paralysis . . . The privileges of parenthood (the preschool child) . . . General anesthesia (history) . . . Incidents in a medical fairy tale (Dionne chronological tables; day by day records of caloric intake, and foods used; weekly weight chart, etc.) . . . The physical Franklin (the most versatile American) . . . Cancer among princesses and queens . . . Heart disease of children . . . The three household thermometers . . . Saving eyesight in industry . . . Hernia . . . Seasickness . . . The dilemma of the disfigured matron (medical mystery tale) . . . William Harvey . . . The "Why" of vaccination . . . Curious stories about health . . . Glands (their influence) . . . Parting is such sweet sorrow (teeth) . . . P.A.D.: Prevent Asphyxial Death . . . New Books on health . . . Questions and answers.

In "School and Health":

What children need training in mental health . . . A first grade's journey to healthland . . . Detroit has new school health program . . . Pupil guide sheets in health education in senior high school . . . A teacher's self measurement scale . . . New health books for teachers and pupils.

To those who might write about school health education:

The editor of the School and Health Department of *Hygeia* will be pleased to receive articles dealing with the solution of concrete and practical health education problems in the school. Articles must not exceed 1,000 words in length. Stamps should accompany manuscripts to insure their return if rejected. All articles accepted will be paid for at regular rates. Address Editor of School and Health Department of *Hygeia*, 67 Clyde Street, Newtonville, Mass.

Hygeia, March, 1936—Published at 535 N. Dearborn St., Chicago, Ill., *Hygeia* for March, 1936, contains the following:

"The Story of Louis Pasteur" (helpful comment on the new motion picture) . . . Cancer is curable (what every one should know) . . . How diseases came with the white man to America . . . Some facts and fancies about babies . . . Steps in the detection and alleviation of deafness (illustrated) . . . The backward child (behind the wall of the retarded mind) . . . The blue man (against the careless use of silver preparations) . . . The tired child (symptoms of chronic fatigue) . . . Sex education (what shall I tell the child) . . . Meeting emergencies at home (ingenuity in devising "hospital conveniences") . . . The traveler's food and drink . . . Preventable deformities . . . P.A.D. (more prevention of asphyxial death) . . . Varicose veins (cause and cure) . . . The case of the coryphee's cousin (again the doctor's Scotland Yard) . . . Hideyo Noguchi (a master mind of medicine) . . . The skin in health and disease . . . These teeth of mine . . . A milkmaid and vaccination . . . Famous lives that ended before forty (due to preventable causes) . . . New books on health . . . Questions and answers.

In "School and Health" will be found:

Am I as a teacher a well adjusted person? . . . Health and safety suggestions for the school register . . . The health education program in the public schools of Baltimore . . . Practical hygiene in the junior high school . . . Safety games for Baltimore children . . . New health books for teachers and pupils.

HEALTH EDUCATION

The following have been reported in *Library Index*, National Health Library, 50 W. 50th St., New York, N. Y.:

Chamberlin, R. C., R.N. Teaching personal hygiene. *American Journal of Nursing* (New York City), 36:167–71, Feb., 1936.

Collins, L. B., and Welling, J. B. Educational services of the Detroit health education

club. *Journal of Health and Physical Education* (Ann Arbor, Mich.), 7:76–79, 120–21, Feb., 1936.

Cooper, Edith. The reaction of the education authorities, teachers, and parents to the teaching of biology and health education in the schools. *Health and Empire* (London), 10:320–23, Dec., 1935.

Harrington, M. H. Dental health week in Delaware. *Journal of the American Dental Hygienists' Association* (Stratford, Conn.), 10:10–15, Jan., 1936.

Holstrom, E. M., R.N. Dental health education. *Bulletin of the Iowa State Association of Registered Nurses* (Des Moines), No. 37:10–11, Sept., 1935.

DATES AHEAD

"Coming Conventions" as announced on the last page of every issue of the *Journal* merit attention for local press use. A request to national gatherings for information as to speakers and officers from your city and state may give usable information. And some of these conventions may have abstracts of addresses by home town people, or you may be able to secure abstracts direct. Your editors may be glad for information about the speakers.

In April the new Early Diagnosis Campaign gets under way. While this is primarily a project of tuberculosis associations there are angles of common interest for various types of health agencies. Further information from state and local tuberculosis associations.

April 12—When the first dispensary was opened in Philadelphia in 1786.

April 15—Organization of the National Child Labor Committee, 419 4th Ave., New York, N. Y.

April 25 to May 2—National Boys' and Girls' Week, 35 E. Wacker Drive, Chicago, Ill.

April 26 to May 2—Better Homes in America, Purdue University, West Lafayette, Ind.

May 1—One of our national moving days.

May 1—May Day and Child Health Day.

May 10—Mothers' Day, long a day of sentiment and flowers, is now becoming a day to emphasize "Make Maternity Safe." See Maternity Center Assn., 1 E. 57th St., New York, N. Y.

May 12—Birthday of Florence Nightingale, 1820.

May 12—National Hospital Day. Write to American Hospital Assn., 18 E. Division St., Chicago, Ill.

May 15—American Assn. of Medical Social Workers founded in 1918. Address: 18 E. Division St., Chicago, Ill.

May 18—World Good-Will Day. Consult Federal Council of Churches, 105 E. 22d St., New York, N. Y.

May 21—First Red Cross in the United States in 1881. Address: Washington, D. C.

May 24–30—National Conference of Social Work, Atlantic City, N. J. Write to 82 N. High St., Columbus, Ohio.

All of the above offer possibilities for presentation in staff meetings, of chances for good will greetings to executives of other agencies in your city or state, and of utilization in speeches or press material. Some of them will suggest active collaboration between health agencies.

Working details for some of them are given in "News Almanac for Social Work." Community Chests and Councils, 155 E. 44th St., New York, N. Y. *50 cents.*

Brief reports of what any one has done with any of the above dates will be welcome.

NEW

Bulletin, International Committee on Open Air Schools, 7 Freiligrathstrasse, Bielefeld, Germany. Five issues, largely for promotion of Third International Congress on Open Air Schools, 1936, are being distributed by the Office of Education, Washington, D. C.

Publication of *International Nursing Review* has been resumed by International Council of Nurses, 14 Quai Gustave Ador, Geneva, Switzerland. 8 Swiss francs per year.

FOR EDUCATION AND REFERENCE

"Catalog of 600 Books on Foods, Housing, Beverages, Management" is a classified bibliography which may be of use to camps, sanatoria, hospitals,

etc. Includes nationality cook books, diet and nutrition, housekeeping, etc. Probably includes fad books. Hospitality Guild, Stamford, Conn. *Free.*

"Caring for the Sick in the Home." John Hancock Mutual Life Insurance Co., Boston, Mass. 30 pages. *Free.*

Practical suggestions which will enable the attendant and the family to supplement most effectively the services of the visiting nurse, and to assist in giving the care according to the doctor's orders.

"The Facts About Certified Milk." American Assn. of Medical Milk Commissions, 1265 Broadway, New York, N. Y. *Free.* What, why and how. Our attention was directed to "the attractive typography and persuasive contents of this brochure."

"Health Publications of the American Medical Assn.," 535 N. Dearborn St., Chicago, Ill. *Free.*

Sex education . . . child welfare . . . health plays . . . nutrition and diet . . . nose, ear, throat . . . physical education . . . mental hygiene . . . dental hygiene . . . periodic health examinations . . . public health (communicable diseases; sanitation and hygiene) . . . health in education . . . conservation of vision . . . Hygeia . . . cancer . . . protection of research . . . miscellaneous . . . nostrum evil and quackery . . . Bureau of Medical Economics . . . medical education and hospitals.

"Helpful Information for Diabetics: An Authoritative Guide." 14 pages. Dept. of Health, New York, N. Y.

"Home Hygiene Classes in an Official Agency," by B. L. Cawthorn. *Public Health Nursing,* 50 W. 50th St., New York, N. Y. Nov., 1935. *35 cents.* Teaching "groups of mothers in selected districts to give care to the members of their own families and to help their neighbors in sickness."

A new series of illustrated questions and answers have been released beginning March 2. Good for newspapers and for house organs. *Free* from Health News Service, 22 E. 40th St., New York, N. Y.

"Pocket Caloric Index: To Aid in Gaining or Losing Weight," by E. B. Tietz. Reprinted from *Hygeia,* this 6 page, illustrated, stiff card folder is an ingenious device to help take the make believe out of gaining or losing weight. Given the number of calories daily, as physician directed, the folder makes it fairly easy to select food items, to decide upon quantities, and to keep track of the daily allowance. American Medical Assn., 535 N. Dearborn St., Chicago, Ill. *10 cents.*

"Pointers on Polio." A radio address, 2 articles, and a reading list. 11 pages. *10 cents.* American Medical Assn.

"Reading Ways to Health," by B. E. Schildwachter. The library in a sanitarium. *Hospitals,* 18 E. Division St., Chicago, Ill. Feb., 1936. *25 cents.*

Two to three sheet mimeographed releases, supplied by League of Red Cross Societies, 12, Rue Newton, Paris, 16, France:

Convulsions: . . . The food of the growing child . . . Carl von Linnè (Linnaeus, a pioneer of medicine).

"Wearing Glasses," by W. B. Lancaster, M.D. "Reasons for wearing glasses, common mistakes in the way glasses are worn, suggestions for their care." 23 pp. 21 illus. *10 cents.* American Medical Assn.

BOOKS AND REPORTS

A Review of Selected Books of Interest to Public Health Workers

Mazÿck P. Ravenel, M.D.

OUR review of books on public health presented last year after an interval of several years was received with sufficient enthusiasm by our readers to warrant repeating the survey this year.

The following recommendations and comments upon books published during 1935 are based chiefly on reviews in our *Journal*. The *British Medical Journal, The Lancet,* the *Journal of the American Medical Association,* and other magazines have been consulted, but it must be borne in mind that we avoid books on clinical subjects because our primary interest is public health.

THERE have been a number of small books and reports on the various phases of child health during the year, but few works of outstanding importance. Among those specially worth while is *Your Child Is Normal,* by Grace Adams, Covici-Friede, which covers the first 7 years of childhood. It can be thoroughly recommended to parents for their own benefit as well as that of their children. It is pleasingly written and easy to read. *The Mother's Encyclopedia,* compiled and edited by the Editors of the *Parents' Magazine,* Reynal & Hitchcock, is a real encyclopedia of 959 pages by some 130 authors. It contains a vast amount of useful information on bringing up children, and is commended by specialists. A report of the Committee on Maternal Welfare of the Philadelphia County Medical Society has been published, entitled *Maternal Mortality in Philadelphia.* This is an excellent study and concludes that the usual type of statistical study does not seem to be able to clear up the question of the relatively stationary figure at which maternal mortality stands. This report might well be classified differently in this review, but a study of it indicates that it is as important to the child as it is to the mother.

From children we more or less naturally turn to nursing. The year has brought out a number of very useful reports and books. *An Activity Analysis of Nursing,* by Ethel Johns and Blanche Pfeferkorn, is a report of the Committee on the Grading of Nursing Schools. It is particularly valuable for those interested in teaching and making curricula, but is useful for all who are in any way concerned with good nursing. *The Art and Principles of Nursing,* by Amy Elizabeth Pope and Virna M. Young, Putnam, deals largely with the technic of professional nursing. It is well done and is recommended to nurses as well as to physicians. *The Art of Public Health Nursing,* by Edith S. Bryan, Saunders, is a book of which it is hard to say too much in praise. It is recommended not only to public health nurses, but to all women in the nursing field. An excellent report has been given on the grading of nursing schools

called, *Nursing Schools—Today and Tomorrow,* which discusses the faults which may be found with our present schools, what we should expect of the professional nurses, why there are so many unemployed nurses, etc. This report is recommended not only to nurses and physicians, but to all public health workers who of necessity come into contact with the problems here discussed. Nurses for some time have been feeling the necessity of knowledge of psychology and mental hygiene. *Introduction to Psychology,* by Edward S. Robinson and Virginia Kirk, Macmillan, written with special applications to nursing and nursing interrelationships, has been designed to fill this need. There have been a number of new editions of books for nurses which have stood the test of time and criticism. *Nursing Mental Diseases,* by Harriet Bailey, Macmillan, 3rd edition, is most highly recommended, the author having had many years' experience with this branch of her profession. *Communicable Diseases for Nurses,* by Albert G. Bower and Edith B. Pilant, Saunders, 3rd edition, is highly recommended. *Medical Diseases for Nurses,* by Arthur A. Stevens and Florence Anna Ambler, Saunders, 2nd edition, is also commended.

The year has seen a number of excellent books on nutrition, a subject which for some years has been attracting more and more attention. *Your Meals and Your Money,* by Gove Hambidge, McGraw-Hill, is a popular presentation of diets as related to income, built on data obtained largely from the workers in nutrition of the U. S. Department of Agriculture. It is authoritative and written in pleasing style. *Diet and Physical Efficiency,* by Howard W. Haggard and Leonard Greenburg, Yale University Press, is an excellent study of the question of fatigue from the nutritional standpoint, which the authors measure from the respiratory quotient. It is adapted to general readers as well as those who have more special training. *Nutrition and Physical Fitness,* by L. Jean Bogert, Saunders, has reached its 2nd edition. The information it contains is useful and reliable as far as nutrition goes, but it says little about physical fitness. It is written in such terms as to make it useful to the laity as well as to nurses and student dietitians. *Child Nutrition on a Low-Priced Diet,* by Mary Swartz Rose and Gertrude M. Borgeson, Columbia University Press, is an excellent study and merits careful consideration, being of interest in child development. Mrs. Rose needs no introduction, and her name alone speaks for the value of this book. *The Vitamin B Requirement of Man,* by George R. Cowgill, Yale University Press, is a scholarly, though somewhat technical, study of experimental, mathematical, and historical researches on vitamin B and beriberi. *Nutrition Work with Children,* by Lydia J. Roberts, University of Chicago Press, is a revised edition. The original work appeared some 9 years ago and has been a standard reference through the years. This book is especially valuable in that more than half of it is given to prevention and treatment. It will doubtless hold its place as a standard reference until another edition appears. In June, 1935, the *Quarterly Bulletin of the Health Organisation, League of Nations,* published a report by Et. Burnet and W. R. Aykroyd, on *Nutrition and Public Health,* which is very interesting, and is addressed primarily to public health authorities. It is comprehensive, including discussion of dietary standards, food supply, differences in dietary habit, and their effect on nutrition. It gives a strong plea for education in nutrition and gives examples of public health nutrition

work. The opinion of an expert is: "Never before has so much of interest regarding nutrition and public health been brought together in such a readable form."

For the past 3 years amebiasis has attracted much attention. A masterly book, *Amebiasis and Amebic Dysentery,* by Charles F. Craig, Thomas, is of more than usual importance. No one anywhere is more entitled to write on this subject than the author. He has given us an excellent discussion of the history, epidemiology, incidence, life cycle of the endameba, and methods of transmission. It is hard to recommend this book too highly. Sharing with amebiasis in attention is infantile paralysis. *Poliomyelitis: A Handbook for Physicians and Medical Students,* by John F. Landon and Lawrence W. Smith, Macmillan, though small, covers the ground in excellent fashion. It claims only to be a summary for practical use and can be heartily recommended. Another excellent study is *Infantile Paralysis,* by George Draper, Appleton-Century. This is a summary written for the layman. It emphasizes the importance of consulting a physician at the onset of any suspicious symptoms. It is also a useful book for the physician and the medical student, as it gives the points on which the laity wishes information in direct and simple language.

The study of allergy has not given rise to as many books this year as might have been expected. The phenomenon is still attracting much attention and our knowledge of the extent of its influence seems to be broadening, but no new work has come to our attention. New editions of two books on the subject have come out: *Allergy and Applied Immunology,* by Warren T. Vaughan, Mosby, is a classical, readable study, which can be highly recommended as a safe and sound guide for the general practitioner. *Recent Advances in Allergy,* by George W. Bray, Blakiston, is one of the most complete and well written reviews which have appeared. Both of these books represent not only a study of the literature, but a large experience.

Mental hygiene is generally regarded as an abstruse specialty. It is a difficult subject but books are appearing which should be read by the average practitioner and even by laymen. Certainly every physician and health officer comes across cases which can be understood thoroughly only through the study of mental hygiene. *Mental Hygiene for Effective Living,* by Edwin A. Kirkpatrick, Appleton-Century, is intended to familiarize the uninitiated with the meaning of mental hygiene. The author approaches the subject through an understanding of what is normal. He makes the mistake of overemphasizing the ease with which the principles of mental hygiene may be applied. It is, however, a commendable book. *Psychology and Health,* by H. Banister, Macmillan, has many excellent features. It will be of service to health officials, though not to the extent which might be wished. It is evident that public health service would be improved if individual citizens understood the relation of sentiment to socially approved activity. The book shows that there is a definite hazard to the well-being of the general public as a result of the incidence of mental instabilities and psychiatric disorders. The improvement in mental health of individuals will lighten the tax burden and diminish the tension of living which are subversive of group welfare. *Training in Psychiatric Social Work at the Institute for Child Guidance,* by Sarah H. Swift, the Commonwealth Fund, is a good description and discussion of the psychiatric social work training program at the Institute for Child Guidance, New York City, during the years 1927

to 1933. *Making Our Minds Behave*, by William S. Walsh, Dutton, has many good features. The author is a successful writer with a marked ability to use easy American vernacular. He gives much sound and sensible material in interesting style. *Keeping a Sound Mind*, by John J. B. Morgan, Macmillan, is an excellent presentation of material to aid the student in establishing desirable mental and emotional habits and acquiring the right attitude toward life.

A number of extremely interesting historical books have appeared. *A Short History of Some Common Diseases*, by divers authors, edited by W. R. Bett, Oxford University Press, is described as an original venture in medical literature, which it is. In spite of some errors, it is extremely interesting and useful. Biographies of great medical men necessarily contain much medical history, and this is true of *The Life of Sir Robert Jones*, by Frederick Watson, Wood, a story of a great man whose gifts were recognized during his life. He was known in this country almost as well as in England. A book which is philosophical and has been a best seller is *Rats, Lice and History*, by Hans Zinsser, Little Brown. It is the result of philosophical musings, laboratory experiments and a wide experience in studying contagious diseases, especially typhus. A thoroughly delightful book is *Memoirs of a Small-Town Surgeon*, by John Brooks. Wheeler, Stokes. In addition to the great interest which attaches to biographies as such, this book gives a wonderful picture of the old Massachusetts General Hospital and the very unusual group of men who were teaching at Harvard about 1880. A less complete story but also most interesting is told of the famous teachers under whom the author worked later in Europe after leaving Boston. It is one of the most delightful books which have come to the reviewer's desk during the year. A book which can be praised most highly is *Some Notable Epidemics*, by H. Harold Scott, Wood. Not only is this book delightful as history, but is useful as a study of epidemiology. Another biography which contains a vast amount of medical history is *Fifty Years in Public Health: A Personal Narrative with Comments*, by Sir Arthur Newsholme, George Allen & Unwin, Ltd. An unusual book is *The Story of Medicine in the Middle Ages*, by David Riesman, Hoeber. This scholarly work leaves one with a different impression of medicine in what has been called the Dark Ages. Few of us realize the enormous amount of good which was done during this period. *The Advance of Science*, edited by Watson Davis, Doubleday Doran, is a more or less contemporary history covering a vast field which is taken care of from week to week in the *Science News Letter*. It is an excellent book to have on one's shelf for reference.

There have been a number of new editions or books on bacteriology, but only one new text. Among the notable new editions is *A Textbook of General Bacteriology*, by Edwin O. Jordan, Saunders, which has reached its 11th edition, and maintains the high standard set by its predecessors. Portions of it have been largely rewritten and all of it has been brought up to date. *Handbook of Bacteriology*, by Joseph W. Bigger, Wood, has reached its 4th edition. It is one of the best of the handbooks and has evidently filled a need. A new type of book on bacteriology is *Agents of Disease and Host Resistance, Including the Principles of Immunology, Bacteriology, Mycology, Protozoölogy, Parasitology and Virus Diseases*, by Frederick P. Gay and Associates, Thomas. This is a monumental work and the material is given in an interesting and well organized fashion.

Not many books have appeared on epidemiology. A notable one, *Epidemics and Crowd Diseases*, by Major Greenwood, Macmillan, is called an introduction to the study of epidemiology, but apparently intended for the laity. It is delightfully written, rich in classical allusions, gives much history, and can be highly recommended not only for its erudition, but for its general interest. *A Geography of Disease*, by Earl Baldwin McKinley, George Washington University Press, is a laborious compilation of geographical incidence of diseases arranged by countries. It is most valuable for the purpose intended, and was issued as a supplement to the *American Journal of Tropical Medicine* by Williams and Wilkins.

A notable event of the year was the appearance of *Sedgwick's Principles of Sanitary Science and Public Health*, by Samuel C. Prescott and Murray P. Horwood, Macmillan. While it does not and cannot replace the original text, it is a well done piece of work and deserves success. *Preventive Medicine and Hygiene*, by Milton J. Rosenau, Appleton-Century, has come to its 6th edition and is extensively rewritten. While it still has some of the deadwood which the author claims to have eliminated, it is a most valuable text, and will undoubtedly retain the position it has held for so long. *Twelve Hours of Hygiene*, by F. L. Meredith, Blakiston, is a book designed for a one hour course for college freshmen. It contains much useful material and is good for ready reference. *A College Textbook of Hygiene*, by Dean F. Smiley and Adrian G. Gould (rev. ed.), Macmillan, has been very favorably reviewed. It is an attractive text, but rather rudimentary for college students. *The Principles of Preventive Medicine*, by Hutt and Thompson, Methuen, comes to us from England in two volumes. This is a sound and comprehensive treatise written in the best English manner and can be highly recommended for advanced students. *Personal and Community Health*, by Clair E. Turner, Mosby, has reached its 4th edition. It has been considerably enlarged and brought up to date. It can be recommended for college level groups.

The Principles and Practice of Medicine, by Sir William Osler; revised by Thomas McCrae, Appleton-Century, has enjoyed an unprecedented popularity since 1892, when the first edition was published, and the appearance of this revision is an event in medical circles. We believe that every health worker should have a good book on medicine at hand and know more about actual disease. *Dynamics of Population*, by Frank Lorimer and Frederick Osborn, Macmillan, covers a wide field of especial interest to sociologists. It is useful reading, but rather heavy unless one is a specialist. *The Theory of Play*, by Elmer D. Mitchell and Bernard S. Mason, Barnes, appeared first in 1923 as "The Theory of Organized Play." It has been entirely rewritten and as it now appears is the most thorough and interestingly written treatise on the theory and administration of play. It is designed especially for educators. *Stand Up and Slim Down*, by Ettie A. Hornibrook, Doubleday Doran, is a worthwhile book for laymen and physicians, considering as it does, a number of the subjects often discussed by persons without much knowledge of the fundamental facts. *Medicine Marches On*, by Edward Podolsky, Harper, is an interesting book containing a large amount of information correctly, though rather sensationally, given. It has value in that it will bring those who will not ordinarily read medical literature to an understanding of many useful facts, in spite of its style not being such as we care for. A most useful book for all public health workers is *Social Work Year Book*, 1935, edited by Fred S. Hall, Russell Sage Founda-

tion. It covers practically every phase included under public health work. It is an invaluable reference book, giving correct information on the numberless existing agencies, with the names and addresses of the executive directors. A curious book, the result of deep thinking by a number of well known men, is *The Frustration of Science*, by 7 authors; foreword by Frederic Soddy, Norton. It is, we hope, unduly pessimistic, but certainly makes one think. *Heredity and Disease*, by Otto L. Mohr, Norton, is the outcome of a series of lectures given by this distinguished Swedish geneticist at Harvard in 1933. It is deep reading on an interesting and important subject, and forces the conclusion that the day is past when environment can be excluded from the discussion of heredity as far as human affairs are concerned.

Fundamentals of Dairy Science, by Associates of Lore A. Rogers, Reinhold Publishing Corp., has reached its 2nd edition. The first met with a warm reception, and there is no doubt that the second will be similarly welcomed. We have not received any books on housing, as such, though this matter is being much discussed in every country. *The Housing Program of the City of Vienna*, by Charles O. Hardy and Robert R. Kuczynski, the Brookings Institution, is a presentation of one of the most remarkable social experiments of modern times. It should stir all health workers in this country. The question of water supplies is treated constantly in textbooks on bacteriology, engineering, etc. The journals have many articles approaching the subject from its various aspects. One notable book, *Swimming Bath Water Purification*, by Wilkinson and Forty, 2nd edition, Contractors' Record, Ltd., has appeared, which in the opinion of the reviewers, is better than anything on this subject which America has yet produced. *Elementary Human Anatomy, Based on Laboratory Studies* by Katharine Sibley, Barnes, is written especially for students of physical education, and is a real contribution to educational aids for the special group for whom it is designed.

There is a group of books on subjects constantly under discussion not only from the medical and public health standpoints, but by sociologists and philanthropists. *Drugs Against Men*, by Henry Smith Williams, McBride, is an excellent exposition of the subject. Though it deals in facts, we cannot help feeling that it draws a slightly exaggerated picture. *What About Alcohol?* by Emil Bogen and Lehman W. S. Hisey, Angelus Press, is a strong book, one which is now being pushed by certain organizations for use in schools. It is one of the best of its class, but in the opinion of the reviewer, is strongly tinctured with exaggeration. *A New Deal in Liquor: A Plea for Dilution*, by Yandell Henderson, Doubleday Doran, gives a considerable amount of useful history as well as scientific facts concerning alcohol and its effect on the human body. There is also an interesting discussion on the use of euphorics, such as tea, coffee, chocolate, etc., and alkaloids. The main thesis of the book is that alcohol should be taken in dilute form. *Science and the Public Mind*, by Benjamin C. Gruenberg, McGraw-Hill, is an account of an investigation into the place of science in relation to adult education and how activities in that field should be stimulated. It is written in a clear, crisp and interesting style, and can be commended. An excellent book by one of the best writers on biology, unfortunately now dead, is *Biology for Everyman*, by Sir J. Arthur Thomson, Dutton. We know of no one who has written more delightfully on biological subjects than the author, who did much to popularize the subject and to combat the narrow mindedness which

brought about the disgraceful trial of a young teacher in Tennessee. *What You Should Know About Heart Disease,* by Harold E. B. Pardee, Lea & Febiger, has reached its 2nd edition, which speaks for its usefulness. It is written in a helpful and optimistic tone which will bring comfort to many. It is designed chiefly for laymen and is a valuable contribution in a limited field. As an aid to the understanding of a much discussed, yet unsettled, subject, *Lactobacillus Acidophilus and Its Therapeutic Application,* by Leo F. Rettger, Maurice N. Levy *et al.,* Yale University Press, is useful and should be mentioned. The book contains so much of interest as to well repay the reader. *Standard Classified Nomenclature of Disease,* edited by H. B. Logie, 2nd ed., Commonwealth Fund, is an aid in the bookkeeping of public health. The index has been installed in more than 120 hospitals, and 27 national organizations have approved it. It contains more than 15,000 items.

The following are worthy of brief mention by title and author because of their acceptance as indicated in the numbers of copies ordered by members through the Association's Book Service: *Physical Defects—The Pathway to Correction,* American Child Health Association; *Big Problems on Little Shoulders,* by Carl Renz and Mildred Paul Renz; *Common Sense for Mothers,* by Mrs. John S. Reilly; *Health Dentistry for the Community,* Edited by Michael M. Davis; *Health Education in Senior High Schools,* by Dorothy Ruef; *Modern Motherhood,* by Claude Edwin Heaton; *Recording of Local Health Work,* by Carolina R. Randolph and W. F. Walker; *Methods and Materials of Health Education,* by Fannie B. Shaw and Jesse Feiring Williams.

In the advertising pages of this *Journal* eleven publishers have taken space to announce books they believe will interest our readers. Some have been or will be reviewed in this *Journal.* Attention to them is invited.

Injury and Incapacity—*By H. Ernest Griffiths, M.S. (Lond.) F.R.C.S. Baltimore: Wood,* 1935. 270 pp. Price, $5.00.

The present work was written with special reference to industrial insurance. The author has investigated a large number of cases and traced them from the date of injury to the time of resumption of full work. In this, he has differentiated between the opinion expressed by a surgeon to a hospital, which usually gives a much more favorable prognosis than does the man's own panel doctor who is confronted with the length of time before the man ultimately resumes his work.

The book aims to establish a basis for estimating the probable period of incapacity for any given injury, in any particular patient, having regard to his present employment and his ability to earn in another employment. Some 50,000 consecutive cases of accidents obtained through courtesy of a large insurance company, having cases all over the British Isles, and the author's personal study of some 15,000 cases, form the basis of the discussions.

Operations for the physical requirements of workmen have been classified into 24 types, and, in indexing, a thousand or so occupations show which operations come under each of the types. Thus Type 1 is "heavy, laborious work," for which the physical requirements of the workman, as related to each important part of his body, are laid down—hands, thumb, fore-arm, feet, ankle joint, spine, abdomen, vision, nervous system, etc.

The disabilities following injuries to various parts of the body are divided into 12 chapters which comprise 193

pages. A thorough subject index accompanies. There are no illustrations. Descriptions are tersely given and very well captioned and sub-headed, so that perusal is easy and the chief facts are readily gleaned. The average period of incapacity at different ages of life, and for both heavy work and light work, is given in 90 short tables integrated with the subject matter throughout the book. Only limited consideration is given to females.

To anyone interested in the subject of capacity, incapacity, compensation, and physical types of workmen, and especially surgeons, general practitioners who necessarily encounter surgical mishaps, claims adjusters, medical economists, etc., this would appear to be an indispensable volume. Much is said about preferred methods of treatment.

EMERY R. HAYHURST

Lobar Pneumonia and Serum Therapy—*By Frederick T. Lord, M.D., and Roderick Heffron, M.D. New York: Commonwealth Fund, 1936.* 80 pp. Price, $1.00.

The Commonwealth Fund has rendered a distinct service in publishing this brochure. It is dedicated to the late Dr. George H. Bigelow, who initiated these studies in 1931. The writer once heard the late Sir William Osler, in a public address, say that we were able to cure no greater number of pneumonia cases today than were cured in the time of Hippocrates. It is gratifying to know that this is no longer true.

The serum treatment of pneumonia began in Germany with the experiments of Neufeld and Händel, in 1910. Cole and Dochez, in 1913, were the first in the United States to use it. It was unsatisfactory until 1924, when Felton's method of concentration of sera was introduced. Most of these concentrated sera for Types I and II are bivalent.

We now recognize some 32 types of pneumococcus, but 96 per cent of all cases of lobar pneumonia are due to the pneumococcus, and Types I and II produce approximately one-half of these cases. The death rate averages 25 per cent when the infection is due to Type I, and 41 per cent when due to Type II. The use of the appropriate serum has reduced the mortality in Type I cases to 11 per cent and Type II cases to 27 per cent.

At the beginning of the Massachusetts study it was advised that serum treatment be begun on all cases as soon as the clinical diagnosis was made, but it is now recommended that typing should be done, since the patients may be given a serum which is not specific and at the same time may sensitize them. However, the danger of serious allergic reaction is believed to be exaggerated. In 956 cases treated in Massachusetts, there were 4 deaths due to the use of serum, of which only 1 was due to an allergic reaction and 3 to thermal reactions. We are advised to take precautions against allergic manifestations by studying the history and giving eye and skin tests for sensitivity to horse serum. Unfortunately, it is not practical to give the benefits of specific treatment to children for reasons which are detailed. The different methods of typing are described, and that of Neufeld is generally preferred.

A short appendix gives the details of the Massachusetts cases. While this brochure contains only 80 pages of text, every page has great value and we wish that it could be put into the hands of every practising physician.

MAZŸCK P. RAVENEL

Vitamins in Theory and Practice —*By Leslie J. Harris, D.Sc., Nutritional Laboratory, University of Cambridge, England. New York: Macmillan, 1935.* 240 pp. Price, $3.00.

This book comprises the subject matter of 4 popular lectures given at the Royal Institution in London in 1934. The purpose of the lectures was to present in a popular fashion the main facts known about vitamins (those for a long time elusive minute constituents so essential to growth, function, and freedom from disease, but now being analyzed in the laboratory and more definitely classified).

The small book gives a historical sketch of the discovery of the vitamins, a description of the known vitamins, A to E, with a brief discussion of the diseases resulting from a deficiency of them. There are also set forth the articles of diet as well as other contributory factors which furnish the essential vitamins to promote health and prevent deficiency diseases. Chapter XI of the book treats of Dietetics and indicates how corrections may be made in ordinary diets to offset or cure deficiency diseases.

The writer shows familiarity with the work and writings of those who made possible our knowledge of vitamins, and the data set forth are in line with the latest accepted theories and known facts in regard to them.

The book is well printed, indexed and illustrated. JAMES WALLACE

Child Psychiatry—*By Leo Kanner, M.D., with prefaces by Adolph Meyer and Edward A. Park. Springfield, Ill.: Thomas,* 1935. 527 pp. Price, $6.00 postpaid.

This is an encyclopedic treatise in a field which is coming more and more to the attention of the general practitioner and the pediatric specialist. It is the first book in the English language to cover comprehensively the many phases of the child's personality from the objective standpoints of psycho-biology and psycho-pathology of childhood.

The material is based upon a wealth of experience of the author in studying large numbers of children at the Harriet Lane Home for Invalid Children, the Pediatric Department of the Johns Hopkins Hospital, and the Henry Phipps Institute of Psychiatry. The whole child in his many relationships is under consideration.

The book affords the pediatrician a method of approach to the personality disorders of childhood and gives him an insight into the problems arising within both the child and his environment. One wishes that as much attention had been given to treatment from the child guidance standpoint as to the diagnosis and pathology of childhood disorders. RICHARD A. BOLT

Length of Life—*By Louis I. Dublin, Ph.D., and Alfred J. Lotka, D.Sc. New York: Ronald Press Co.,* 1936. 400 pp. Price, $5.00.

This valuable book presents in nontechnical fashion the more important and interesting facts and relationships derived from life tables of different times and places, and from associated information.

After a general discussion of the age span, containing such interesting references as that to Drakenberg, who, according to seemingly reliable records, died at the age of 141 years, the book proceeds to a brief explanation of the elements of the life table: survivors, deaths, death rates, expectation of life, and auxiliary data.

Time changes in the length of life are traced, beginning with the fragmentary data of pre-Christian Egypt and Rome, where the expectation at birth was perhaps 20 to 30 years, down to 1929–1931, when the calculated expectation in the United States was 59 years for males and 63 for females.

Under "Biological Aspects of the Life Table" are discussed mainly qualitative changes in mortality, such as the shifting preponderance of specific

causes of death with varying age, time, and rate of natural increase of the population. While the campaign against degenerative diseases is not disparaged, the increase in mortality from these diseases is properly termed an "honorable defeat," since these ailments reflect in large measure the normal wearing out of bodies preserved from more preventable death during the earlier years of life. [Moreover, since old persons are no longer permitted to die of old age, they must of necessity turn to mortality rubrics still countenanced.]

A brief discussion of inheritance and longevity summarizes researches indicating that longevity is strongly influenced by heredity. The authors contend, however, that "the increase in longevity attainable by effective use of existing resources in the control of the environment still exceeds by a good margin the difference in longevity between the most favorable and the least favorable heredity groups" in the study cited. In a review of the contribution of medical science, a new edition is presented of Dublin's hypothetical life table, originally published in 1928; the anticipated expectation of life at birth is, in this book, increased from the earlier estimate of 64.75 years to 69.93—practically, the biblical three score years and ten.

Longevity is next considered in relation to physical impairments and occupation. The professional groups appear to have hardly half the mortality of unskilled workers, even after age-adjustment of rates. Physicians have above average mortality. Airplane pilots on schedule flying have a fatal accident rate of 25 per 1,000—6 times the general mortality of males of like age!

A chapter on Application to Population Problems outlines the meaning of "true" birth and death rates, as defined by Lotka, and shows how the "true" rate of natural increase is hardly half the crude. The authors estimate that in 1920 the natural increase was 5.4 per 1,000 population; in 1930, 2.8; in 1933, minus 2.06; and in 1934, minus 0.6. In other words, the birth and death dates of the latter 2 years have operated toward a declining population. On the basis of stated assumptions, the authors forecase a maximum population for the United States of 154 millions, to be attained about 1990.

The rest of the book is devoted to applications of the life table to economic problems (life insurance, economic value of the wage earner, and replacement of industrial equipment) to insurance life tables, and to the technic of life table construction.

An extremely useful feature of the book is found in the Appendix, which gives 32 pages of life tables. These, with the text tables, provide "what is probably a more extended collection of life tables than can be found in any other single source." In the list are about 50 original tables for the United States and for individual states based upon the 1930 census, including a few for colored, urban, rural, and a series for foreign countries, some as recent as 1930–1933!

In the opinion of the reviewer, certain geographic differences are taken somewhat too seriously in the book. It is believed that the urban-rural contrasts may be misleading to some readers, in spite of the qualification made in the case of cancer, that "the urban excess may be more apparent than real." The implication on page 96 (and a less specific statement in paragraph 3 of page 100) that in the U. S. Registration Area, the age compensated urban mortality is 31 per cent in excess of the rural has a dubious foundation in the absence of more general intra-state residence allocation. The apparent rural advantage arises

largely from low rural rates recorded in southern states and in other states recently admitted to the registration area, where crude rural death rates run as low as 5 and 6 per 1,000—half the urban rates, or even less. (See, for example, Oklahoma, Arizona, and South Dakota in Table I, *U. S. Mortality Reports*, 1932.) Whether the very low rural death rates in these states imply incomplete death reporting or merely the absence of rural hospital facilities is difficult to say; nevertheless, the favorable expectations of life, as calculated for some of these states, probably require further justification.

In general, however, any flaws which one might pick in this book are trivial in relation to the value of the book as a whole. Everyone with a broad interest in public health or demography should read it. The achievement of the authors in presenting a technical subject soundly, in language understandable to persons of moderate intelligence and education, will best be appreciated by those who have examined the original publications underlying the book. A. W. HEDRICH

Foods and Beverage Analyses—*By Milton A. Bridges. Philadelphia: Lea and Febiger,* 1935. 246 pp. Price, $3.50.

This book of special value to physicians, dietitians, and students of nutrition will be welcomed by all who want reliable and up-to-date data on the composition of foods and beverages. The tabular material covering nutritive, mineral, and vitamin values and alcoholic analyses is the most complete that has ever been published in a concise and usable form. For the first time there have been gathered together data regarding the analyses of commercial canned and packaged foods. A large staff of assistants and investigators have searched international records, and where data on common foods were lacking original analyses have been made. Analyses of well known commercial products have been obtained through contact with the manufacturers.

The first six chapters, including 39 pages, are largely descriptive, covering briefly proteins, fats, and carbohydrates, giving their properties, utilization, nutritive requirements, and deficiencies and sources. They also include tables giving the water and cholesterol content of common foods, caloric requirements, and average height-weight data. Chapter 7, including nearly half of the book (116 pages), consists of a table giving the carbohydrate, protein, fat, and caloric value of the most comprehensive list of both natural and manufactured foods ever published. A unique feature of this and other tables in the book is the presentation not only of the percentage composition, but also of the number of grams of each element in the average portion of food served as designated in common household measures. Chapters 8 and 9 (12 pages) give in a similar way the analyses of special dietetic foods and strained foods. Chapters 10 to 12 (30 pages) are devoted to the inorganic constituents of foods. Brief descriptive paragraphs are given on the properties, requirements, utilization, and sources of mineral elements, and acid-ash and alkaline-ash foods. A table gives the percentages and grams, in average served portions, of calcium, phosphorus, iron, copper, manganese and chlorine in over 440 foods. The iodine content of a large number of foods is given in a separate table of 8 pages. The remainder of the book is devoted to vitamins, and the composition and fuel value of alcohol beverages, together with the qualitative ingredients of various common mixed alcoholic drinks.

An extensive bibliography as late as of July, 1935, is appended.

D. BREESE JONES

Principles of Hygiene—*By Thomas A. Storey, Ph.D., M.D. (rev. ed.) Stanford, Calif.: Stanford University Press,* 1935. 524 pp. Price, $3.50.

This book is a revised edition of the one issued in 1924 and, as the writer states, most of the chapters have been rewritten. This work differs from most books on hygiene as in the words of the author it deals with "the principles of hygiene." A better title might be one which would suggest that it deals with the factors which provide the background for hygiene. The author has in preparation a volume on the practice of hygiene, and, as he says, the present volume deals with the principles of constructive hygiene and of defensive hygiene, the principles on the one hand which influence production, improvement and maintenance of health, and those on the other which regulate the defense of health and prevention of disease.

In summing up these factors the author covers a wide field of embryology, physiology, biology, anatomy, bacteriology, and heredity, the last named being discussed at considerable length. The writer is prone to divide and subdivide his subject, perhaps for the convenience of his students. Hygiene as a whole he divides into autonomic and voluntaristic, the former being represented by reflexes and animal instincts for self preservation and the latter by conscious effort to promote as well as preserve health. The voluntaristic is becoming more and more scientific in character. The principles of constructive hygiene are enumerated as reproduction, heredity, nutrition, excretion, exercise, rest, and environment. Defensive hygiene may be autonomic or voluntaristic, as it is constituted by the influences which have to do with the defensive hygiene of heredity and those which protect good heritage and prevent injury and disease.

The book is valuable for those (particularly students) who wish to acquaint themselves with the underlying bases of hygiene; its appeal, however, to the readers of popular information on hygiene will likely be limited.

JAMES WALLACE

Medical Mycology: Fungous Diseases of Men and Other Mammals —*By Carroll William Dodge. St. Louis: Mosby,* 1935. 900 pp. Price, $10.00.

Recent years have brought a greatly increased interest in the infectious diseases of man caused by fungi higher than the bacteria, as evidenced by a marked increase in the literature dealing with this subject. Much of this literature is confusing because the authors are medical men who have not given sufficient consideration to the identification or nomenclature of the organisms with which they are dealing, or mycologists who have not sufficiently considered the evidence regarding the pathogenicity of the organisms they are describing. There has been such an eagerness to discover new species of pathogenic fungi that a common sense attitude toward taxonomy has often been lacking and Koch's postulates have often been ignored. As a result, the journal literature dealing with medical mycology is almost useless to all but specialists in this field of science, and a comprehensive work which would integrate and interpret this literature would be of great value in the clinical laboratory.

The present work only partly serves this purpose. The author, a distinguished mycologist, has laboriously prepared a most comprehensive summary of the now quite extensive literature. He deals almost exclusively with the mycological aspects, barely touching upon the medical, and is concerned primarily with questions of classification. He presupposes a knowledge of general mycology on the

part of the reader, the introductory chapter being too brief and condensed to provide a proper background for what follows. The author is a "splitter" as far as classification is concerned, and by accepting large numbers of "species" which have been separated by very slight or obviously variable characters, by creating a number of new genera and new combinations, he has aggravated rather than improved a situation which is rapidly becoming intolerable.

Nevertheless this book will be of inestimable value as a reference work for the specialist or serious student of medical mycology. It provides a complete and well arranged list of all of the fungi reported as pathogenic to man, with their descriptions, and a bibliography which must be almost complete, covering as it does the rich Italian and Spanish literature, which is not available to most of us, as well as the usual German, French, and English. Disagree as one may with the nomenclatures and classifications adopted, he will find it necessary to keep this book on his desk.

ARTHUR T. HENRICI

The Facts About Certified Milk —*American Association of Medical Milk Commissions. 1265 Broadway, New York City*, 1936. 15 pp. Free.

This very attractive brochure describes the origin and development of certified milk, outlines the requirements for its production, discusses pasteurization of certified milk and vitamin D certified milk, and gives a list of cities where this superior grade of milk may be obtained. Every health officer and all persons interested in milk sanitation will find this pamphlet worthy of perusal.

J. A. TOBEY

Living Along With Heart Disease —*By Louis Levin, M.D. New York: Macmillan*, 1935. 126 pp. Price, $1.50.

This short treatise is, as its title implies, written for the use of the layman. It covers, in interesting simple language, a discussion of such factors as the fear of heart disease, the definition and types of heart disease, and special discussion of such types as "leaky" hearts, myocarditis, hypertension. It discusses heart pain, the general treatment in a non-medical way, and concludes with sections on questions and answers, and on the "philosophy" of heart disease.

An interesting, informative, and worth while discussion.

CHARLES H. KEENE

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH.D.

Foods that Fight—We who believe that any food fit to eat is fit to eat in combination with any other food will be interested in this British discussion of "compatibilities." All the old-granny ideas about milk and fruit, etc., are dragged out and discussed with due solemnity. That the conclusion finally reached is that there is no scientific basis for the superstitions will be lost upon the faddist who will assume where there is such a dense smoke raised by food quacks there must be some fire, despite the tone of this article.

ANON. The Compatibility of Foods. J. State Med. 44, 2:103 (Feb.), 1936.

What to Do With Our Chronic Sick?—Recent state surveys show that 1 of 10 in the population, and nearly 1 of 3 of those over 40 years of age, suffer from some chronic disease. Most communities have inadequate facilities for their care, and they are found scattered about in many institutions. The author discusses the rôle of out-patient clinics, need for special hospitals for care and study of chronic illness, the types of patients best cared for at home, and suggests the necessity for community planning if wise care for all and economical use of community resources are to result.

BOAS, E. P. A Community Program for the Care of the Chronic Sick. Hospitals. 10, 2:18 (Feb.), 1936.

Problem Drinkers—A discussion of the effect of excessive drinking on different types of people and of the treatment necessary to bring about a change of habits. Case studies are given to illustrate the author's points. This is condensed from a book in preparation.

DURFEE, C. H. Understanding the Drinker. Ment. Hyg. 20, 1:11 (Jan.), 1936.

Diphtheria Immunization Abroad—Further success with toxoid immunization in British health districts confirms experience here.

CHESNEY, G., and PARISH, H. J. Alum-Precipitated Toxoid in Diphtheria Immunization. Brit. M. J. 3917:208 (Feb. 1), 1936.

Psychiatric Clinics—The annual directory of psychiatric clinics in the United States prepared by the National Committee on Mental Hygiene lists the clinics available in each state, the location of each, the name of the director, the personnel composing the clinic staff, and the time of weekly clinics.

CLARK, M. A. Directory of Psychiatric Clinics in the United States, 1936. Ment. Hyg. 20, 1:66 (Jan.), 1936.

About Undulant Fever—A member of the original "Mediterranean Fever Commission" gives some interesting sidelights on the history of undulant fever abroad and here, reporting an increase in the disease in England. The author quotes 20 per cent as the incidence of infection among cows in Great Britain.

EYRE, J. Undulant Fever. J. State Med. 44, 2:64 (Feb.), 1936.

Arguments for Diphtheria Immunization—Canadian experience indicating the value of diphtheria prophylaxis is reported upon.

FITZGERALD, J. G. Diphtheria Prevention, Methods and Results. Canad. Pub. Health J. 27, 2:53 (Feb.), 1936.

Vaccination Against Infantile Paralysis—In North Carolina 1,400 children applied for vaccination against poliomyelitis; slightly more than half were vaccinated, the remainder were controls. No poliomyelitis developed in either group. To obtain conclusive results ten times the number would

have had to be included. Local reactions occurred in half the vaccinated children, general reactions in 3 per cent.

GILLIAM, A. G., and ONSTOTT, R. H. Results of Field Studies with the Brodie Poliomyelitis Vaccine. Pub. Health Rep. 51, 7:160 (Feb. 14), 1936.

Tackling Parents' Problems at Close Quarters — Opportunities for the psychologist as a consultant for the visiting nursing service are set forth. This paper has the especial virtue of becoming modesty in presenting the claims of this specialty.

KETTERLINUS, E. The Rôle of the Psychologist in a Public Health Nursing Program. Pub. Health Nurs. 28, 2:85 (Feb.), 1936.

Experimental Poliomyelitis—Experiments are reported indicating that in monkeys poliomyelitis infection does not take place through the intestine. This does not support the epidemiologic inference which implicates water and milk as an occasional vector of the disease.

LENNETTE, E. H., and HUDSON, N. P. Failure to Infect Monkeys with Poliomyelitis Virus through Isolated Intestinal Loops. J. Infect. Dis. 58, 1:10 (Jan.-Feb.), 1936.

Tenants for Public Housing Projects—The manager of First Houses, built by the New York City Housing Authority to replace a row of ancient East Side tenements, tells how the first tenants were chosen from the waiting lists, and how they have responded to the responsibilities placed upon them for maintenance of living standards and care of equipment.

LUMSDEN, M. First Families. Survey Graphic. 25, 2:103 (Feb.), 1936.

Fear and Childbearing—Does discussion of maternal mortality terrify childbearing women, hence becoming itself a cause of increased mortality? This question is answered in the affirmative, with the further observation that it may also affect the developing baby and be a cause of neonatal mortality. As might be expected, the discussion is philosophical and not supported by research.

NEWSHOLME, H. P. An Aspect of Maternal and Infant Ill-Health. Pub. Health. 49, 5:174 (Feb.), 1936.

Education and Appendicitis—As in other studies this Cincinnati summary indicates the health educational opportunities in appendicitis. Delay and the taking of purgatives are largely responsible for the deaths. Adolescents and young adults are the most susceptible, and males outnumber females 2 to 1.

REED, M. R., *et al.* A Statistical Study of 2,921 Cases of Appendicitis. J.A.M.A. 106, 9:665 (Feb. 29), 1936.

About Clinic Economics—Two years ago objections to unfair competition of Dayton, Ohio, clinics with private practice resulted in the closing of all clinics. Medical care for the indigent was provided by government supported services supplied through private physicians on a fee basis or by city doctors on salary. When relief funds grew scarce certain clinic services were resumed at a decreased cost to the public.

Ross, M. Why Not Do Without Clinics? Survey Graphic. 25, 2:81 (Feb.), 1936.

A Head for Mental Hygiene—The need of, and opportunity for, a federal, official head for the mental hygiene program, some day to be an acknowledged part of public health administration. Important.

TREADWAY, W. L. The Place of Mental Hygiene in a Federal Health Program. Pub. Health Rep. 51, 3:181 (Feb. 21), 1936.

About Inspecting Canned Goods—A practical discussion of food inspection by a British official who compliments the American canners.

WHITE, C. F. The Inspection of Canned Foods. Pub. Health. 49, 5:180 (Feb.), 1936.

ASSOCIATION NEWS

AMERICAN PUBLIC HEALTH ASSOCIATION
SIXTY-FIFTH ANNUAL MEETING
NEW ORLEANS, LA.
OCTOBER 20–23, 1936

Please note that the dates of the 65th Annual Meeting at New Orleans previously announced as October 19–22 have been changed to October 20–23.

Instead of opening Monday and closing Thursday as ordinarily, the meeting this year will open Tuesday and run through Friday afternoon.

THE HEALTH CONSERVATION CONTESTS

THE City and Rural Health Conservation Contests for 1935 are now in the final stage. This is the 7th year of the city contest inaugurated in coöperation with the U. S. Chamber of Commerce in 1929, and the 2nd of the rural contests for full-time areas. As in other years, the urban contests are made possible through the aid of leading insurance companies, and the rural contests through the help of the W. K. Kellogg Foundation, Battle Creek, Mich.

Entries in the city competition this year number 234, representing cities in all but 3 states, and in the rural contest, 159 counties and districts are participating. The total population of the cities entered in the urban contest is more than 23,000,000, and of the rural contest a population of 6,000,000 is included. As in previous years, the city contest is divided into cities with varying population groups, while the rural contest is divided into geographic areas.

The Awards Committee this year is comprised of W. S. Rankin, M.D., of the Duke Endowment, *Chairman;* W. F. Walker, Dr.P.H., New York, N. Y.; A. J. Chesley, M.D., St. Paul, Minn.; Prof. C.-E. A. Winslow, New Haven, Conn.; T. F. Cuneen, Insurance Department, U. S. Chamber of Commerce; Henry D. Chadwick, M.D., Boston, Mass.; and George B. Darling, Dr.P.H., Battle Creek, Mich. This committee, among other measures, will take into account the adequacy of health facilities and their support and the quality of work done in safeguarding milk and water supplies, in disposing of sewage and in other usual health department practices.
